MOTOR TRUCK v. WAGON FOR FARM HAULAGE.—Mr. K. Pahl read the following paper:—"Horses are essential for effectively working the farm, but as means of transport they are too slow if a farmer has to cart any great distance. I recommend the 1-ton truck for the average farmer. In harvest time wheat can be carted straight from the harvester; there is no loss of wheat from wet weather, and reaping will be done more quickly because the team can work without interruption. During seeding, super, &c., can be carted while the team works the fallow, thus increasing production. Where haulage has to be done off the farm, it pays to use the truck; it is cheaper and takes less time." Mr. A. Ramsey said in busy seasons and when wheat was plentiful each man had to wait his turn to get his wheat unloaded, and that would prevent the man

with the truck from carting many more loads that day. With a truck one had to work faster to cart the same amount as the man with the team. The teamster took his time, delivered his load without any worry of blowouts, engine trouble, &c. He considered the wagon better and less expensive for general haulage. Mr. J. Pahl said in a new hundred, where water and other commodities had to be carted long distances, the truck was essential so that the team could do the work on the farm while the truck did the hauling. It could also take the place of a car for a conveyance. On more established farms he favored the wagon. Mr. V. Jonas favored the wagon. He considered the life of a truck too short to be an economical investment, and the upkeep was too great for the average farmer. In new hundreds a truck would be essential to effectively work the farm. Mr. R. Paxton considered the use of either truck or wagon was governed by conditions. His experience with a truck was that he could cart quicker and cheaper than with horses. Work could be proceeded with on the farm while carting was being done with the truck, thus keeping up with operations. The truck would cost more when repairs were needed and so become more expensive, but, at the same time, a horse might die, which would probably be as expensive as repairs to a motor. Mr. S. Barber had had considerable experience with both methods of transport, but favored the wagon. One load a day would be equal to four truck loads with less wear and tear. Blowouts in the hot weather had to be reckoned with, which in itself, apart from the time wasted, was expensive. General repairs soon mounted up and made a truck very expensive. Mr. C. Masters thought a truck too expensive for general farm work. Wear and tear and upkeep was much more than for the wagon. Horses might die, but young horses could be reared cheaper than trucks could be repaired, thus the wagon would be cheaper on established farms. In new districts probably a truck could be used with advantage. (Secretary, Mr. C. Masters, Verran.)

RUDALL (Average annual rainfall, 12.07in.).

September 9th.—Present: 13 members and two visitors.

**MAKING A HOME IN THE MALLEE.**—Mr. A. Jericho read the following paper:—“Seldom does a farmer pay enough attention to the geographical position of the land he intends to occupy, as well as the class of land, water supply, and other items which may bring success or failure to the venture. Any section after being allotted must be worked according to conditions typical to that class of land. *Light Soils.*—Under this heading most of the land of Eyre Peninsula in the lower rainfall areas can be dealt with. Fortunately, of late years this land has proved that it is a profitable venture to deal with. Labor and capital are two important factors in the mallee. A farmer should not expect more than a fair rate of interest on his outlay the first three years. The first expense in clearing the lighter soils is negligible; but before it is brought up to a standard that will give profitable returns it will be found that it has cost more than the heavy soils. This is an important factor often overlooked by inexperienced settlers. In opening up a new section either a log or a roller is effective, but after the first year usually the disc plough plays an important part in dealing with black sticks. Usually farmers wait for that day to come, thinking only a hot gale from the north will give them a good burn; but the risk of the fire getting out of control is too great, and very good burns can be obtained with steady winds from other quarters. A commendable practice, worthy of serious consideration, is the fallowing of new ground. The drift problem

should receive more consideration while the original scrub is on the land. Any land likely to drift should not be cleared in too large areas. Experience has taught that it is less costly to clear land at a later date than to clear too much in the beginning and start the land drifting. Last, but by no means least, good wind breaks should be left around the proposed homestead site. A farmer neglecting this item may be successful on his selection for 20 years and then find his home and sheds in line with the drift, which is not only uncomfortable but expensive." (Secretary, Mr. J. McKinnon.)

#### SMOKY BAY (Average annual rainfall, 10.44in.).

Meeting held August 23rd. Present: Mr. G. Lovelock (chair) and 14 members. Matters of local interest were brought forward for discussion. (Secretary, Mr. K. Harrison.)

#### TARAGORO.

October 2nd.—Present: 14 members.

**CARE OF MACHINERY.**—Mr. E. James read the following paper:—"One of the biggest problems of the farmer to-day is the cost of production, and the high prices we have to pay for machinery makes a big inroad on the returns from the farm, therefore every farmer should give his machines proper care and treatment, which lowers the cost of their upkeep and lengthens their life of service. There are three important points: housing, keeping all nuts tight, and proper lubrication. All woodwork should receive a coat of boiled oil each year and paint every three years. For lubrication of all implements I recommend a light-bodied motor oil, because in the summer it will resist the heat and during seeding, generally cold, it will run freely to the bearings. When putting away harvest machinery clean all congealed oil and dust from around bearings. Fill the bearings with oil, as rust will attack a worn surface if not covered with a film of oil. Place a block under the off-side of the comb of the stripper or harvester to prevent sagging. When a binder is put away on the transport, lower the big wheel on a block to take the weight off the frame, and put a coating of thick oil or grease on the knoter. With the drill or combine, thoroughly clean out the super and seed boxes before putting them away, and treat the bearings the same as stated before. The most abused implements are the plough and cultivator. Sometimes when a part has to be taken off to be mended or replaced nuts cannot be unscrewed owing to rust, and they have to be cut off, which means the loss of a bolt, a coating of paint every few years would prevent that. Another asset is a blacksmith's shop on the farm. A handy man can do minor repairs and save expense, but it is essential that all the machinery should have systematic oiling and careful driving to prevent deterioration."

On October 15th Mr. W. J. Spafford addressed the Branch on the subject "Agricultural Practices." There were present 12 members and 24 visitors.

**PREPARING FOR HARVEST.**—At the meeting held on November 6th, and attended by 18 members, the following paper was read by Mr. W. Whittaker:—"In preparation for harvest, there should be careful consideration as to machinery, horses, and tractor. Horses should be given at least a fortnight's spell from work and their harness, chains, &c., put in perfect condition. The head should be taken off the tractor and cleaned, valves seen to, big ends tightened up, and all grease, oils, and worn parts replaced with new. The first machinery generally used for harvest is the binder, which should be in good condition so as to get the hay cut, stooked, and stacked before reaping. The knife should be sharpened, knoter re-oiled, big wheel, fans, canvasses, pole, swings, chains, &c., replaced, and transport wheels removed. The second machine used is either the stripper, header, or harvester. Out of these I prefer the stripper, because it is the only machine that will stand up to rough conditions. The harvester or header are satisfactory in a good year, but when we have to go over much ground for a small amount of wheat the stripper is the most payable. In preparing the stripper, the belt should be well oiled with used tractor oil. If this is done no resin will have to be applied. The set screws in the beaters should be tightened, forks placed in good order, and chains, swings, and belt replaced. If the reaper is used, a winnower must also be used. I prefer a power winnower because all heads are thrashed, reaping can be done in cold weather, and a much better sample is obtained. Belts should also be oiled, elevators tightened, sieves replaced, thrasher in good condition, and forks oiled. To have a successful harvest, so far as the machinery is concerned, all parts should be kept well oiled, a good standard harvesting oil should be used, and all nuts and bolts should be tightened or replaced as soon as they are broken or become loose."

**GARDENING.**—Mr. E. Rudland read the following paper:—"I propose to outline a few points of interest of the most popular form of gardening as generally practised on farms, in a comparatively light rainfall area. First and foremost is the selection of plot for the proposed garden. I favor a slight depression in the soil, because the ground in these parts is usually more fertile and has a tendency to retain moisture longer than that situated on a rise or slope. Remove all stumps. Cultivate the plot with a single-furrow plough and root the soil to a good depth. This will save many disappointments.

A garden that has been poorly cultivated will never return the yields that one will receive from deeply ploughed land. As the natural soil is rarely fertile enough to produce heavy yields, it is advisable to apply and work in a heavy dressing of cow manure. In order that the plants will be well protected from live stock, a good fence should be erected, and if in an exposed place, reinforce with a breakwind. Paths should be built at least 6 in. above the level of the beds and graded to drain water off. When the garden has been marked out in sections scatter about 2 in. of fresh horse manure to provide warmth, then dig in lightly. As regards the growing of vegetables, full details of seasonal crops can be found in the weekly papers. Nearly all root vegetables require a deep rich soil, and they respond readily with the slightest attention. For cabbages and cauliflowers, plenty of room must be allowed—at least 2 ft. each way. For early results plant seeds at the end of February. This will give strong plants a chance with the first rains. Do not plant all seeds at the same time, but endeavor to secure a steady flow of vegetables for the house. Cauliflowers need a little assistance to produce good heads; the general practice of experienced gardeners is to gather the outside leaves and lightly tie them; this protects the heads from the sun and dust. Peas are easily grown, and respond well without much attention. The summer garden needs more care, and plants grown as early as possible will produce fruit when it is needed. Cucumbers, pumpkins, and all marrows need abundance of water. With tomatoes more care is needed, both in growing and watering. They should be given plenty of water to keep them growing healthily. If the plants are pruned and trained they will produce a splendid amount of fruit. The ground should be kept loose, and if kept moist black spot will not develop. Flowers do not appear to be popular here, but nothing is more pleasing than a well-grouped display. Even a few blooms brighten the homestead; it does not matter a great deal about the varieties, as each has his own taste, but a little energy in this direction will be amply repaid, both to the owner and the visitor." (Secretary, Mr. T. Winters, Cleve.)

#### WALLALA.

September 10th.—Present: 13 members and three visitors.

Mr. K. W. Neild read a paper, "Harvesting Machinery." He said harvesting machinery could be divided into two classes, the harvester and header and the stripper and winnower, each of which had its own particular advantages. The header and harvester had been brought almost to perfection during the last few years and were now extensively used owing to the speed and economy with which they could handle the crops. Their disadvantage was that they deteriorated quickly and were not so successful when used on the rough stump land, which constituted a large area of the farming lands of their district. That fact, together with the adverse seasons experienced of late, had influenced many farmers in favor of the stripper. The main advantages of that machine were that it was easier to operate, had less wear and tear, and efficiently handled very light crops. In normal years, where there was a very large area to be reaped, it must be done in the cheapest possible manner, and for this reason the header or harvester should be given serious consideration. It eliminated the risk of large losses due to rain during the harvesting period and considerably reduced the labor required to harvest the crop. On the other hand, although the use of the stripper entailed much more work, it was very useful on stump land and for reaping the poorer crops in very dry years. Assuming that the average farmer of their district cropped 700 acres annually, he would require two implements to harvest the crop, and he considered that a stripper used in conjunction with a harvester or header would form the most economical harvesting plant for their conditions. The header or harvester could be used wherever possible, and either implement driven by a small engine would make a very efficient winnower. Two men would thus be able to complete the whole of the harvesting operations in a minimum of time. On a one-man farm the harvester fitted with a chaff-saving attachment would enable the farmer to do his own harvesting, and at the same time to save a considerable quantity of feed for the stock. The writer stated in conclusion that the Australian-made machine, being made specially for local conditions, compared very favorably with any other implement. (Secretary, Mr. C. F. Zippel.)

#### WARRAMBOO.

September 9th.—Present: Eight members.

STARTING ON A NEW SCRUB BLOCK.—Mr. F. Chilman read the following paper:—"One of the first essentials in starting on a new block is to find the best site to erect the homestead; preferably the best position is in the centre of the block, not too far off the main road. The reason to get near a main road is you always have the chance of having a fair road to travel on, and then pipetracks and telephones generally follow a main road. Try and choose a sloping piece of ground for the homestead, so that water can drain away from the house; also pick a good patch of soil for a garden

later on. Clear the scrub so that the convenient paddocks can be worked from the stable with the minimum amount of travelling. In clearing light whiststick scrub, I prefer a fairly heavy log. The heavier class of scrub needs a roller to get it down, and there are some blocks where the axe is needed. After the scrub is down, if it is possible, cut all springbacks that are left standing to ensure a clean burn. Clear a fire break around the scrub. That is fairly easily done by burning a break on calm nights, when the fire can be kept under control. After the burning season opens, get the scrub burnt as early in the summer as possible, see that sticks are picked, and cultivate it as soon as possible after burning. Then drill in with a disc drill, preferably after a rain. As soon as possible get the homestead in comfortable order. This again lies with the amount of capital available. But always aim at putting permanent improvements, and in such a way that it is easy to add to them. All fences should be permanent and as many paddocks as possible opening into the stable yard. Sometimes it is necessary to erect a race to lead into a paddock, but always aim at a minimum amount of fencing with handy sized paddocks. It is a good plan to have a couple of 20 or 30 acre paddocks joining the house for the milking. Always aim at making the stables on the south or east side of the house, and there will not be very much trouble with dust and rubbish from the stable blowing around the house. The next essential is to provide a water supply handy to the house and stables. In this district it is difficult to get clay for sinking dams, but there are many places where underground tanks could be put down. Fortunately the Tod main has saved this district from a water shortage. A person need never be idle on a farm, as there is always some improvements to do, such as fencing, making the home more comfortable with outbuildings, gardens, &c. Much can be done to make things comfortable without any great expense if we make the best use of the material we have, such as petrol tins and drums, and there is plenty of stone if anyone is handy with the trowel." Discussing the paper, Mr. W. Morris thought the better method to adopt to provide fire breaks would be to throw the timber back into the rolling for 15ft. or 20ft. all around and thus form a bank of timber on the edge of the rolling which would provide a good bank of scrub to light up on when the burning season opened. If this was done on the day the settler decided what wind was most suitable for him to burn, he could proceed with his assistants to light up the bank opposite to the way he intended the fire to run. It would then gradually burn back into the rolling and make a wider break for the main body of the fire to burn on to. By this method he would not be compelled to go around early in the morning and put out the ends of burning sticks and stumps which so often proved a danger and were the cause of many fires starting in standing scrub. Mr. O. Murphy agreed with the writer in respect to the leaving a small belt of scrub where it was intended to erect the homestead to serve as a breakwind. He was inclined to support the Yadnarie Branch of the Bureau in their resolution asking that the settler be compelled to leave three chains of standing scrub around the holding. This would not only act as a breakwind, but would help to keep drift in check. With regard to a young man starting off "scratch" on a new farm. This he considered was a big handicap and thought that it would be a better proposition if the young man engaged in share farming for a year or two as he would not only gain experience, but would possibly provide a few pounds in cash as a standby when he needed it to start with. Mr. A. Turner considered it was always better to build a heap of timber around the rolling in preparing the breaks. This could be done immediately the scrub was rolled or logged and gave the settler the chance to burn off the rubbish during the cool evenings. Mr. E. Oswald indorsed the remarks of previous speakers in regard to throwing in of breaks around the rolling preparatory to burning. Mr. N. Crawford always made a practice of making a good break on three sides of the clearing and heaped up a break on the northern side to provide a good bulk of stuff for the fire to start from.

On Wednesday, September 10th, Mr. W. H. Brownrigg (District Agricultural Instructor) gave a demonstration of classing the farmer's flock. An address was given by Mr. Brownrigg in the evening on the "Building of the Farm Flock." (Secretary, Mr. E. Adams.)

#### WIRULLA.

August 28th.—Present: Seven members and one visitor.

The meeting took the form of a "Question Box." The following queries were dealt with:—"What is the best variety to grow in place of Late Gluyas?" Members considered that although the variety did not seem to be giving such good results as in the past, they would not advise using another variety as the main crop, because it had proved itself in the past. Federation, Nabawa, and Gallipoli were mentioned as giving good results. "What is the best breed of cow for this district?" Members

**"..... fire has a disinfecting, sweetening, and mellowing effect on 'new' land, which cannot economically be given in any other way"—said Mr. Spafford, Deputy Director of Agriculture.**

In burning stubble the use of a Horwood-Bagshaw Fire Rake is infinitely to be preferred to the ordinary "running burn." Where the stubble is thin the rake will keep the burn going, and is not inclined to be as patchy as a running burn. Again, with a Fire Rake, it is not as necessary to be so careful in the choice of a day for burning. In new country the intensified heat from a Fire Rake will scorch roots, suckers, and shoots, which a running burn is inclined to miss. Further, the Fire Rake, in passing over the ground, misses nothing, collects and burns all the sticks and rubbish, and, in addition, gives the ground a light cultivation stroke.

The Horwood-Bagshaw Stump-Jump Fire Rake is made in light and heavy types, with two or three wheels; four sizes, 12ft., 15ft., 24ft., and 30ft. Write for our illustrated folder, giving full particulars of this implement, also copies of letters from enthusiastic owners. Write now whilst it's in your mind.

Sole Distributors for S.A.—

**The Implement Co.,  
Bank Street, Adelaide.**

***The* HORWOOD - BAGSHAW**  
**Stump-Jump Fire Rake**

favored a dual purpose cow, which would be suitable for beef purposes, since there was not much demand for milk and butter. "Do members think super injurious to the soil?" Most members considered that super was very beneficial, but did not advocate heavy dressings in light rainfall districts. "What is the best depth to fallow in this district?" About 3in. was the general opinion, with the frequent use of the mould-board plough. "What is the best type of horse for farm work in these parts?" The light, clean-legged horse with plenty of bone and good body was most favored; all were against the heavy, hair-legged type. "Is there any period of the season for cutting mallee posts to render them less susceptible to the ravages of white ants?" One member had heard that if fresh cut posts were put in the hole with the smaller end in the ground, the sap would drain out and the posts would last longer. The soft, sappy posts generally appeared to be attacked most by the white ants. One suggestion was that if trees suitable for posts were ring-barked, by removing a strip of bark around the trunk, the trees would not die quickly, thereby seasoning the timber and making it very hard, which might check the ants. (Secretary, Mr. H. Doley.)

## EASTERN DISTRICT.

### (EAST OF MOUNT LOFTY RANGES.)

#### BOOLGUN.

October 2nd.—Present: 16 members.

Sixteen members attended the October meeting, when a paper, "Breeding Horses on the Farm," was read by Mr. T. Stoeckel.

**PIGS ON THE FARM.**—The following paper was read at the November 2nd meeting by Mr. Pfitzner, 13 members being present:—"Many farmers do not pay any attention to pig keeping, but the too-often despised pig is probably, if given proper care and attention, one of the most profitable kinds of live stock on the farm. Farmers should try and breed their own pigs, and in doing so select sows that show length and depth. If possible, try and get sows from large litters, as they are more likely to propagate large litters than those bred from a small litter. It is obvious that the more pigs a sow can produce during her life the smaller per head is the cost of producing them. The sow being the most prolific of all farm animals, is a point strongly in favor of pig keeping. As a sire, it is desirable to use a pedigreed boar. He should be selected from a uniform litter, be of good quality, and should have length and depth, good hams, and strong legs and joints. It is most essential that both sow and boar should not be too fat when mated to get best results. All pigs, other than those fattening for the market, should get plenty of green feed and should be allowed to run out so that they can then forage for mineral foods. It is through pigs that skim milk and swill can be turned to profit. Feeding is quite as important as breed; the best pigs can be spoilt by improper feeding. During winter and cold weather the pigs should have a dry and warm place in which to sleep."

**GROWING LUCERNE WITH BORE WATER.**—A paper on this subject was read by Mr. Woolard at the meeting held on January 29th, which was attended by 11 members. "It is safe to say that on nearly every farm in this district there is a claypan close to the bore. These claypans are suitable places on which to grow lucerne. In the first place, try to get the plot in a position so that it can be irrigated from the bore. Trench the plot 1ft. deep, mixing in at the same time good stable manure. When the trenching is done, remove all hard lumps and stones and leave the plot as near level as possible and with a fine surface tilth. Take a small hoe or stick, make shallow furrows, and run in the seed at the rate of about 10lbs. to the acre. Wait for a favorable rain to start it, and when about 1ft., make the first cut. After cutting, run the water on so that it gets a good flooding. Do not water again until it wants cutting. Always water after cutting, so that you keep the water clear of the leaves." (Secretary, Mr. J. Palm.)

#### BOWHILL (Average annual rainfall, 12in.).

There was an attendance of 21 members and 14 visitors at a meeting held on September 8th. Mr. S. Taylor delivered an address, "Voluntary Pooling." (Secretary, Mr. M. Banks.)

The meeting of October 20th was held at the residence of Mr. H. Just, there being present 28 members and 10 visitors, including the District Agricultural Instructor, Mr. R. L. Griffiths

#### COOMANDOOK (Average annual rainfall, 17.47in.).

Sixteen members and 10 visitors attended the afternoon meeting, which was held at the farm of Messrs. Upton Brothers, when Mr. O. Goddard, of the School of Mines, gave a woolclassing demonstration. In the evening he delivered an address "The Sheep and Wool Industry and Farm Management of Sheep." (Secretary, Mr. W. Trestrail.)

**CLANFIELD** (Average annual rainfall, 16in. to 17in.).

Meeting held September 18. Present: Five members. The report of the delegates who attended the Pinnaroo Line Conference was received and discussed. (Secretary, Mr. W. Pearce.)

**KULKIWIRRA.**

September 9th.—Present: 17 members and three visitors.

**SIDELINES ON THE FARM.**—Mr. Coombs contributed the following paper:—"Sidelines are as necessary as crop growing. I place sheep first because they are useful in so many ways. They provide a considerable amount of revenue, help to keep weeds of many descriptions in check, provide the house with meat, and assist considerably with the fallows in regard to packing. I recommend keeping ewes. There is less risk with them than with dry sheep. I favor the Corriedale breed for this country, and would suggest crossing with either Dorset Horn or Shropshire. Both these breeds give a good lamb that will grow fast and is well liked by butchers. Endeavor to have sheep-proof fences before going in for sheep. Cows are essential for convenience and comfort for the house and the ladies therein. Jerseys are favored because they keep the supply of butter going for a much longer period than the larger breeds. The latter have many admirers and supporters. For these breeds most farmers emphasise the value of the calves for butchering and the amount of butter they will make in the flush period of the year. I am not in favor of keeping a lot of cows unless the farmer has a large family of girls to attend to them. Another point in favor of larger breeds over the Jersey is that when a cow has got to the stage when it is not profitable for milking they have a higher monetary value. This, however, is not so high as it would at first appear. If the amount of food consumed during the life of both breeds over a period of, say, 10 years, is taken into consideration, I think that the Jersey will show to have been more profitable. The Jersey is not a delicate breed and will hold its own with most of the other breeds. If cows are kept, pigs will be found necessary. I have been keeping a Duroc boar for two years now and find them very satisfactory. They keep in better condition during the growing period, are more contented, and easily kept in the sty. I feed barley as the main food, and they are always supplied with whole corn. I use a petrol drum split in halves lengthways and let it in the ground a little way to stop it from rolling over. The best method is to crush the barley and keep it in a self-feeder so that the pigs can help themselves. I keep most of the pigs until they are about 160lbs. to 180lbs. live weight. Fowls are another of the sidelines managed by the ladies. They are easier handled and more profitable than cows. I favor one of the larger breeds of fowls, but if eggs are the main object, then the White Leghorn is not excelled. The larger breeds are more saleable when they have served their term of laying. They can be kept out of the garden, haystack, and farm machinery, and generally lay better during the winter months. The above remarks apply chiefly to an egg-laying strain. I strongly advise every farm homestead to have a kitchen garden. If a record is kept it will prove itself profitable, and vegetables grown on the property are much better than those that are purchased." (Secretary, Mr. H. J. Elliot.)

**LAMEROO** (Average annual rainfall, 16.95in.).

Meeting held September 27th. Present: 12 members. A report of the proceedings of the Annual Congress was given by Mr. C. Wendt and the Secretary (Mr. R. Koch.)

**MERIBAH** (Average annual rainfall, 11.70in.).

At the meeting held on September 8th, Mr. W. Mason presided over an attendance of 17 members. The report of the delegates to the country crop competition was received and discussed. It was decided to hold a local crop competition, for which two trophies valued at five guineas and two guineas have been offered. (Secretary, Mr. E. Carr.)

**MILLENDILLA** (Average annual rainfall, 13in.).

The Secretary, Mr. V. Wegener, gave an interesting account of a trip he had made to New South Wales. There were present 10 members and several visitors.

**MONARTO SOUTH** (Average annual rainfall, 14in. to 15in.).

Meeting held September 20th. Present: Mr. A. Braendler (Chair) and 29 members. Messrs. Hein and Kuchel reported on the Annual Congress. (Secretary, Mr. C. Altmann.)

## NETHERTON.

September 3rd, 1930.—Present: 21 members and visitors.

**SIDE LINES ON THE FARM.**—Mr. Johncock, in the course of a paper on this subject, said side lines such as cows, fowls, kitchen garden, and pigs should prove of very valuable assistance to the household expenses to the man who was just starting on a new block. Cows were essential on every farm, especially where there was a family. Six good cows would produce on an average £90 worth of produce. In the Netherton district it would be necessary to hand feed for six or seven months of the year. Each cow would require 20lbs. of chaff per day, and for the remainder of her fodder should be able to obtain sufficient roughage in the paddock. A paddock of about 24 acres sown with 20lbs. of wheat, 30lbs. of oats, and 90lbs. of super should provide feed for six cows from early June until the end of the year. A cow eating 20lbs. of chaff per day would consume 1½ tons of chaff, at £3 per ton, £5 5s. per cow—for six cows equals £31 10s.; 8bush. wheat at 4s. equals 32s.; 15bush. oats at 2s. 6d. equals 37s. 6d.; 1 ton farm feed £3; 1 ton super £5—£36 19s. 6d. Produce from cows £90; balance £50 0s. 6d. Sale of five calves at £3 each, £15—total £65 0s. 6d. Fowls.—He recommended the White Leghorn. Twenty-five bags of wheat would feed 100 laying hens during the year if birds were allowed free range on the farm; 100 hens should produce £40 worth of eggs each year, less 25 bags of wheat at 12s. per bag equals £15, leaving a profit of £25. It was difficult to give an estimate of the value of the kitchen garden. Where sufficient water was available practically all kinds of vegetables could be grown. Pigs.—Three pigs could be fed on the waste milk from six cows, and with 6bush. of pollard to top off each pig the animals could be used as fresh pork, cured for bacon, or marketed. A pig at five to six months of age should weigh 130lbs.; market value about £4 each pig equals £12. Cost of feeding, 18bush. pollard at 1s. 9d. equals 31s. 6d., profit £10 8s. 6d. Replying to questions, Mr. Johncock said the hens would lay better without running with the roosters if they were locked up. Mr. Wilkin said that sheep kept for rations could be classed as a profitable side line. (Secretary, Mr. C. Wilkin, Yumali.)

## NUNKERI.

September 10th.—Present: 11 members.

**SHEEP DIPPING.**—Mr. C. Grill read the following paper:—"All sheep should be dipped for the destruction of parasites. Merinos about five weeks after shearing and crossbreds about two months. Sheep should not be dipped straight off shears, there is not sufficient wool to hold the ingredients of the dip. A dip 40ft. long, 22in. wide, and 5ft. deep will save a lot of trouble and insure thorough saturation of the fleece, which is absolutely essential if dipping is to be effective. The drainage area for small flocks should be about 16ft. by 18ft., divided into two pens, so that when one pen is full it can be shut off and allowed to drain while the other is being filled. In this district limestone, mortar, and cement, reinforced with wire-netting, is a very suitable building material. There are many ways of getting the sheep into the dip. One way is by having a race lengthways across the edge of the dip and slanting boards at the dip, which should be kept very slippery, so that when sheep pass along the race and step on to the boards they slip into the dip. Another method is by using the same kind of race and a trap door, which has the same effect, but old sheep that have been through a few times are hard to get through the race. The best method is a small pen at the mouth of the dip that will hold about 20 sheep, with other yards made handy for filling up; if one man gets in the pen and catches the sheep by the hind leg and one arm around the neck it is easily pushed into the dip without being knocked about and gets properly treated while in the swim. With the race style of dipping lambs often go too fast and fall in, one on top of the other, or on their backs or sides, or head first, in which case they are liable to take a mouthful of the dip, and it also makes it difficult for the man with the prod to handle them properly. The heads of sheep should be pushed under twice during the swim, care being taken to allow breathing space between each plunge. For the strength of the dip one should be guided by the directions on the packets. Any recognised dip, preferably an arsenical, which is most effective. Keep the bath stirred up from the bottom and see that the scum that accumulates on top is skimmed off. Sheep should be yarded over night and dipping begun early in the morning, and continued only so long that the sheep can dry before night. If this is carried out much fouling of the bath will be avoided, but care must be taken that the sheep are not thirsty, because they are apt to drink the wash or lick up the floor of the draining pen. Dipping should not be carried out in wet, cold weather, as the sheep may suffer from the effects and contract pneumonia, and rain falling on newly dipped sheep may result in scalding and mortality. The rain falling on sheep wet with dip carries particles which should adhere to the wool right down to the skin, resulting in an overdose. When the sheep are quite dry there is no risk. Shade drying, or a cool day makes the dip more lasting in the wool, and prevents scalding which may result if the sheep are turned

out under a very hot sun. To avoid dip-stained wool, the bath should be emptied and thoroughly cleaned out at regular intervals, or when it is noticeable that the dip is heavily laden with dirt which has been washed out of the wool. Rams should be dipped first, then adults, and lambs last. Do not hurry the dipping, but allow sufficient time in the bath for the dip to reach the parasites right down on the skin. If the dipping of sheep is properly carried out there should be no loss or trouble from year to year. Any sheepowner who has had experience with ticks or lice well knows the value of dipping. Lice are the worst offenders, the sheep rub against the fences and logs, or any obstruction that may be in the paddock, until the wool becomes tangled and matted, and in some cases rub themselves bare to the skin, which destroys the whole fleece. With the constant irritation the sheep become very poor, which is detrimental to the rearing of fat lambs. The Compulsory Dipping Act is very essential, for careless sheepowners with lousy sheep are of great annoyance to their neighbors." (Secretary, Mr. F. Ling.)

#### OVERLAND CORNER (Average annual rainfall, 10.58in.).

The meeting of September 1st was held at the residence of Mr. J. Loffler, there being present Mr. T. Atkinson (Chair), 14 members, and two visitors. An address, "Diseases of Wheat," was delivered by Mr. R. L. Griffiths (District Agricultural Instructor). (Secretary, Mr. H. Loffler, Wirrelyerna, via Morgan.)

#### PARILLA (Average annual rainfall, 13.70in.).

Mr. C. Neindorf presided over an attendance of 12 members at the annual meeting which was held on July 8th. Officers were elected and a programme arranged for the ensuing 12 months.

A further meeting held on September 2nd took the form of a "Question Box." Fourteen members were present.

A previous meeting held on August 5th was attended by 20 members. Members discussed the subject, "Clipping Horses." (Secretary, Mr. C. Foale.)

#### PARUNA.

The monthly meeting was held on September 5th; twenty-six members were present. A debate was held on the subject, "Harvesters v. Strippers," and resulted in favor of the stripper. (Secretary, Mr. F. Sumner.)

#### PATA.

Meeting held September 25th. Present: 10 members and two visitors. Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Wheat Yields in the Murray Mallee Lands." (Secretary, Mr. A. May.)

#### RAMCO.

Meeting held September 8th. Present: Mr. J. Boehm (Chair) and eight members. Mr. Boehm informed Mr. Burroughs that the best time to apply manure to orchards was just before the first irrigation. Other subjects of interest to river settlers were also discussed. (Secretary, Mr. J. Odgers.)

#### WAIKERIE (Average annual rainfall, 9.61in.).

Meeting held September 25th. Present: Mr. E. Rowe (Chair), 11 members, and six visitors. Mr. G. Quinn (Chief Horticultural Instructor) delivered an address "The Codlin Moth," and presented the prizes won at the Waikerie and Ramco Pruning Competitions." Secretary, Mr. E. Rowe.)

## PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1931.

### Eggs for Hatching and Day-old Chickens.

WHITE LEGHORNS ONLY. DELIVERY—JULY, AUGUST, and SEPTEMBER.

#### PRICES—

EGGS—10s. per Setting of 15 Eggs; Incubator Lots, £2 10s. per 100.

DAY-OLD CHICKENS—17s. 6d. per dozen, £6 per 100. Free on rail, Salisbury.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury.

C. F. ANDERSON, Manager.

## YURGO.

September 9th.—Present: Eight members.

**ODDS AND ENDS ON THE FARM.**—The Secretary (Mr. M. Walker) read the following paper:—"The old adage, 'Take care of the pence and the pounds will take care of themselves,' is one that can be applied in many ways on the farm, one of them being the profitable realisation of material which is usually considered to be waste and scrap. The packing around cornsacks—there are many uses to which the hoop-iron may be put, such as spreaders for swingletrees, taking the place of a chain for pulling up the bag lifter, staying swing gates, frames into which can be fitted a kerosene tin bucket, a dozen 18in. lengths fitted into a wooden frame on edge makes a splendid boot scraper. The square fasteners and pins also come in very handy, and one can always find a use for them. The former make good washers for taking up the slack bolts on a scrub roller frame, whilst the mild steel pins are first class for use as rivets, being of various sizes there are often jobs in which they can be used. The sacking covering the bags makes a good cloth for use under the winnower and grader, especially that from off the ends, which frequently is of a much stouter texture than the remainder. Good packing cases should be carefully knocked to pieces, the nails put into a tin, and the boards packed away out of the weather. They will do as well for the job as other timber which would have to be purchased. All scraps of wire should be carefully picked up and put into a heap, or hung up and used to tie on the barb or spring coil when fencing. Shorter pieces come in handy for fastening netting. The waste oil from motor vehicles can be sprinkled on the smithy floor (if on earth). This helps to keep down the dust. It may also be used to advantage if poured around fence posts, gate posts, shed posts, &c., to arrest and prevent decay and check ravages of white ants. Super bags, if cared for and put away, can be used for storing oats and fowls' feed. Never use oil from motor vehicles on any machinery, because it cuts the bearings badly."

Eleven members and 16 visitors attended a meeting on September 29th. Messrs H. B. Barlow (Chief Dairy Instructor) and P. H. Suter (Senior Dairy Instructor) delivered addresses on the subject, "Care of the Cow on the Farm."

At a meeting held on October 27th, with an attendance of 19 members and visitors, Mr. C. F. Anderson (Poultry Expert) delivered an address. An interesting discussion followed.

On November 5th 11 members and visitors toured the district and made an inspection of the crops. An average of six bags per acre was expected for the district. (Secretary, Mr. M. Walker.)

**SOUTH AND HILLS DISTRICT.**

CLARENDON (Average annual rainfall, 33.91in.).

Meeting held September 8th. Present: 20 members and visitors. Mr. J. Spencer addressed the meeting on "Planting Potatoes," and replied to numerous questions. A competition was held, each member cutting three potatoes for seed. The winner was Mr. Rex Potter.

A meeting held on October 5th was attended by 11 members and visitors. Messrs. T. B. Brooks and J. Potter gave reports of the Annual Congress.

A further meeting was held on October 22nd at Mr. D. R. Spencer's homestead. After an inspection of Mr. Spencer's field peas the properties of Messrs. H. C. Harper, L. C. Spencer, and E. A. Harper were visited. (Secretary, Mr. T. B. Brooks.)

INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

Sixteen members and visitors, including a member from the Kimba Branch, attended the meeting held on September 25th, when Mr. R. Hill (District Agricultural Instructor) delivered an address, "Relative Value of Foodstuffs." (Secretary, Mr. H. Lewis.)

LANGHORNE'S CREEK (Average annual rainfall, 14.80in.).

Meeting held September 3rd. Present: 18 members, seven visitors. Mr. B. Caseley gave an address on dairying. Mr. W. Yelland also spoke on the subject, "The Farm Garden."

A further meeting on October 1st was attended by 18 members and four visitors. The delegates submitted reports of the Annual Congress.

Meeting held November 5th.—Present: 20 members and three visitors. Mr. E. W. Pritchard (Botanical Assistant, Department of Agriculture), delivered an address, "Weeds and Grasses of the District."

At the monthly meeting on December 3rd, Mr. A. R. Hilton, B.Sc., of the Murray Bridge High School, gave an address dealing with agricultural education in the United States of America. His address was illustrated with lantern slides. (Secretary, Mr. H. Pollett.)

LENSWOOD AND FOREST RANGE (Average annual rainfall, 35in. to 36in.).

Meeting held September 29th. Present: 13 members. The Hon. Secretary read a paper, "Plant Requirements and Soil Conditions."

Meeting held January 27th. Present: 11 members. A representative of the Producers Distributing Society addressed the meeting on the subject, "Better Marketing Facilities." (Secretary, Mr. B. Lawrence, Lenswood.)

PORT ELLIOT (Average annual rainfall, 20.33in.).

September 24th.—Present: 13 members and three visitors.

PASTURE DEVELOPMENT.—Mr. R. Hill (District Agricultural Instructor) delivered an address on this subject. A keen discussion followed. Mr. Hill said that the best type of pasture consisted of about 25 per cent. clovers and 75 per cent. mixed grasses. He did not advocate ploughing our scrub after clearing before planting clover, because it turned over the sour soil, and also left no covering for the growing clover. Mr. Hay asked what kind of clay subsoil was the better—the light-colored or the darker. Mr. Keen said that he had seen a better stand of Perennial Rye on the lighter. Mr. Hill stressed the value of meadow hay, and said that the time to cut same was just when the growth started to drop. Discussing peas, Mr. Smith said that he had noticed an improvement in growth where he had put pig manure. Again touching on the ploughing of scrub, Mr. Hill said that if this was done, a cover crop of oats should be put in. (Secretary, Mr. H. Lowe.)

Ten members attended a meeting held on November 8th at Mr. H. J. Jagger's homestead, at Inman Valley. Members inspected the sheep and pastures on the property.

A meeting on October 25th was attended by 21 members and visitors, and took the form of an inspection of Mr. Geo. Deplidge's farm, at Waitpinga (Secretary, Mr. A. Lowe.)

#### SCOTT'S BOTTOM.

The meeting on September 6th was attended by eight members. The agenda of the Annual Congress was discussed and delegates appointed. (Secretary, Mr. E. Atkinson, Cherry Gardens.)

October 4th.—Present: Nine members.

FARM MANAGEMENT.—Under the title "Things that should be Cared for on a Farm," the following paper was presented by Mr. A. Martin:—Attend to fences and gates, so that the livestock on the property are kept within bounds. If there are good fences and gates, you will not be troubled with other people's stock if they are allowed on the roads. It is a good plan to clear away 2ft. each side of a fence, so that it will be possible to save the posts from getting burnt in case of fire. Machinery and tools should be kept in the places set apart for them and maintained in good working order. Oiling and greasing of any machine should always be looked to at least once a day to save the wearing of parts. Oil and grease are far cheaper than new parts. Creeks and small gutters should be cleaned out periodically so that if at any time there comes a heavy rain the water can get away and not remain on land that may be required for cultivation or under crop. This paper was discussed, and with "Economy on the Farm" proved very helpful. The following suggestions were made:—Growing own meat; growing fodder for stock; making an early start in the morning; having work planned out; using sharp tools; not overstocking the paddocks; and seeing that all bags, &c., are not left out in the open.

The annual meeting was held at Mr. R. Thorpe's residence on November 1st, there being present eight members. The annual report was read and officers elected.

Items of local interest were discussed at the meeting held at the residence of Mr. Blakeley on December 6th, which was attended by eight members. (Secretary, Mr. E. Atkinson, Cherry Gardens.)

#### SPRINGTON.

A "Question Box" evening was held on September 3rd, 13 members were present.

The meeting on October 1st was attended by 18 members and numerous visitors. Mr. C. A. Goddard (Assistant Wool Instructor, School of Mines) gave a demonstration of wool classing at Mr. B. Forrest's shearing shed. In the evening Mr. Goddard delivered an address on sheep and wool.

Twelve members and visitors attended the annual meeting on November 12th. The Hon. Secretary (Mr. E. Brokate) read the annual report, and officers were elected for the ensuing year.

# CROWN LANDS.

---

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Adelaide.

---

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

---

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

## AGRICULTURAL VIEWS AND COMMENTS.

### MISCELLANEOUS.

#### Agricultural Bureau Conferences.

District Conferences of Branches of the Agricultural Bureau are being arranged as follows:—

River Murray, at Renmark, June 18th (Mr. W. E. Meier, Secretary).

Far West Coast, at Ceduna, July 1st (Mr. E. H. Fear, Secretary).

Upper North, at Willowie, July 15th (Mr. H. A. Crisp, Secretary).

The above Conferences will commence at 10.30 a.m. in each case. Papers and questions for Conferences should be sent to the General Secretary, Agricultural Bureau, about a fortnight prior to the respective dates mentioned.

#### The Dairying Industry.

When discussing a paper on "Ensilage and Grassland Management," read by Mr. R. J. Cleve at the Kalangadoo Conference, Professor A. J. Perkins (Director of Agriculture) impressed upon delegates the importance to the State of the dairying industry. At the present time, he said, there was no industry in the State that was more stable. Unfortunately, the number of cows in South Australia had been regularly declining for the past seven or eight years, and now that they were urgently required by farmers it was very difficult to secure cows at a reasonable price. He hoped that farmers and landholders in the South-East would realise the importance of encouraging the industry and would help to breed cows for the use of farmers in less favored portions of the State.

#### Insects in Flour Bin.

The Government Entomologist (Mr. A. M. Lea, F.E.S.), in commenting on insects forwarded to him for identification from "E. B. P.," Murraytown, says the specimens are larvae and moths of the mill moth or meal worm (*Ephestia kuehniella*) which commonly attacks meals and flours all over the world, and is a serious pest in mills. Burning sulphur should not be used against them as the fumes destroy the gluten, and hence bread could not be made from flour so treated. Heating meals and flours to over 160 deg. will destroy all the insects and their eggs, but the dung and webbing would be left behind as well as the bodies of the insects. The only satisfactory way to get rid of them is to destroy such flours or meals as are already attacked and to steam the bin or otherwise heat it in order to destroy all the larvae. The larvae are to be seen in almost every grocer's store in Australia, and in every flour mill, and they are a constant source of trouble wherever flours and meals are stored.

#### Bloodless Castration of Livestock.

Mr. A. H. Robin, B.V.Sc. (Government Veterinary Officer), speaking at Wirrabara Conference on the use of the Burdizzo pincers as a means of castration, said it was a method that could be recommended. It was now in general use by thousands of stock-owners and was giving satisfactory results; in fact many owners had stated that they would not revert to any other method after having used the Burdizzo. There were many advantages in its favor—its cleanliness, speed, it could be used at any time of the year, it made no wound that could be infected with disease or attacked by flies, and there was no bleeding. Not its least advantage was the fact that the animals received slightest setback. Horses after castration with the Burdizzo could return to work in two or four days, and rams were able to get up and walk away.

# Scientific Farming!

**THAT** is the only proper response to present troubles—**THAT** is the road to solvency and restored prosperity. . .

Economies are necessary, but to cut the application of super in this years farming effort would be a fatal mistake. .

Science and Economy dictate the liberal use of

## W.M.L. EXTRA HIGH-GRADE SUPER

for it lowers costs by increasing yields.

**White Ants Attacking Trees.**

The Woods and Forests Department advises a correspondent at Kybunga, who asked for information as to the best method of preventing white ants attacking trees, that these pests do not attack healthy, vigorous trees. Where it has occurred, however, it has been stated that sheep dung plastered round the stems has been used with very good results. Sugar or treacle with which arsenic has been blended, if placed in the excavations worked by the ants, will kill off large numbers, for they feed upon it readily, and even eat the dead ants which have first succumbed to the poison, so that their numbers are soon reduced.

**AGRICULTURAL INQUIRIES.**

---

[Replies supplied by Prof. A. J. PERKINS, Director of Agriculture.]

---

**Mixing other Materials with Superphosphate.**

"A. D. H.," Yorketown. *Is it advisable to mix superphosphate with some other material in order to get more regular distribution of relatively small quantities during the current season?* The correspondent suggests the use of—(1) Sea sand; (2) finely ground sea shells; (3) seed gypsum. Reply—Of the three, sand, if sufficiently pure, would be the least likely to affect the water solubility of the superphosphate with which it would be mixed. Seed gypsum would come next, and would indeed have no effect whatsoever unless it contained a certain amount of calcium carbonate as an impurity. Finely ground sea shells would, if left long enough in contact with the 45 per cent. superphosphate, probably lead to a certain amount of loss in the water solubility of the superphosphate due to what is known as "reversion." This reversion, however, would be no greater than what occurs when the superphosphate comes in contact with the moist soil containing an adequate amount of lime.

**Barley on Stubble v. Grass Land.**

*Why is stubble land better than grass land for a barley crop? What rotation of crops and what method of working the land for a hay crop is recommended?* "E. G. B.," Maitland. Reply—The general impression in your district to the effect that a better sample of barley is secured when the crop has been sown on wheat stubbles than when it has been sown on grass land is probably correct. To a very great extent "quality" in the barley sample is affected by what is generally known as the "condition" of the land; that is to say, that land which in any way has been forced along a crop and to lead to relative rankness in growth, usually shows inferior quality in the sample of Barley. Probably in this direction the main

# The **Fordson** does an 8-horse job ... at lower cost

**WITH** the new Fordson, under average Australian conditions, you can plough 12 acres per day against an 8 horse team's 5 acres; you can harrow 88 acres per day against the 8 horse team's 40 acres; you can scarify 28 acres per day against the 8 horse team's 14 acres, and you can harvest 15 acres per day against the 8 horse team's 10 acres per day . . . . .

And at much lower cost.

Work for which you would formerly need the help of one or two men, you can do yourself with the Fordson, with no time lost for feeding and care of teams. You can work the Fordson all day—and all night too if necessary.

Your nearest Ford Dealer is anxious to tell you about the New Fordson Tractor—its increased power and many improvements. Ask him to give you actual figures on the cost of Fordson field-work in your own district.

difficulty is excess of available nitrogen during the growing period of the barley crop, and in this connection, there would usually be less available nitrogen on wheat stubbles than in recently broken grass land.

Preference is for the following rotation:—

Wheat—Barley—Grass—Bare Fallow.

If an oatens hay crop is grown upon stubble, the most effective method of increasing the hay yield would be—

- (a) to sow the oats as early in the season as circumstances permitted; and
- (b) to subsequently topdress the crop after seeding with not less than  $\frac{1}{2}$  cwt. sulphate of ammonia or nitrate of soda.

---

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

### Paspalum and Couch Grass.

“H. L. L.,” *Inman Valley*, asks information as to the feeding value of *paspalum* and couch grass. Reply—*Paspalum dilatatum* is a strong-growing forage plant of fairly high feeding value, but in temperate climates, and particularly in those parts where the winter is cold, this grass is only a hardy forage plant, giving some feed in the summer which is not very nutritious. Couch grass is extremely hardy, grows well in sandy soils and is very fattening for sheep, but does not produce a great bulk of forage, and is not a particularly good milk producer. Both *paspalum* and couch grass can be established by seed amongst scanty pasture provided—(1) The soil is loose enough for the drill to enter it, and (2) the seed is drilled in to a shallow depth in November after having been closely fed down and when there is enough moisture present to germinate the seed. Better results, of course, follow seeding on properly cultivated land.

### Waste Currants as Food for Stock.

“E. C. D.,” *Clare*, asks what is the value of waste currants as a food for livestock. Reply—A sample of currants was submitted to the Director of Chemistry, who has supplied the following analysis:—

|                                         | Per cent. |
|-----------------------------------------|-----------|
| Moisture . . . . .                      | 10.02     |
| Ash . . . . .                           | 2.84      |

|                                         | 100.00    |

It is almost impossible to compare this foodstuff with any of the other well-known foodstuffs because the protein content is so low, and much of the carbohydrates consists of sugar. If the sugar is digestible by farm livestock, currants could be compared with some other feeds, for fattening purposes at all events, on their starch equivalent values as follows:—If maize is worth 81.5, wheat bran is worth 48.1, and the waste currants 75. On this basis, if the currants are to replace maize at £7 10s. a ton, the currants would be worth about £6 17s. a ton, but with bran at £3 15s. a ton the currants would only be worth about £5 17s. a ton. Neither of these comparisons can be taken as strictly correct, because the currants contain so much less protein than the other two foodstuffs. If currants are to be used to full advantage by farm livestock, they should be fed in conjunction with other foodstuffs rich in protein, such as peas, lucerne, subterranean

**Rations for Fattening Sheep.**

*If wethers and lambs are fed heavily on oats and dry feed, is there any danger of impaction and would it be advisable to add linseed nuts to act as a laxative?* "D. A. L.," Auburn. Reply—If the sheep are getting roughage as a picking of dry feed in the paddocks, there should be very little risk of impaction killing or retarding the development of the animals, but trouble might be experienced if all of the feed is carted to the sheep. Sheep nuts would keep the sheep healthy, because of their laxative effects, but they are very expensive when compared to other foodstuffs, and one should get equal results in keeping the animals free from impaction, and at a much less cost, by using bran or molasses. As a matter of fact, there is a foodstuff procurable near Clare, which will probably do the job better than those already mentioned, i.e., the small waste currants held by the Clare Packing Shed. If these can be purchased at a reasonable figure, they could be fed at the rate of  $\frac{1}{2}$  lb. to  $\frac{1}{4}$  lb. per sheep per day, and with some oats as well as roughage, the animals would probably keep in good health and fatten very readily.

**Cultivation of Badly Drifted Soil.**

*A field of fairly firm land which does not usually drift was fallowed and the heavy winds have blown the loose soil from large areas right down to the depth of ploughing. Should the field be reploughed or only cultivated?* Reply—Our experience with areas of fallow which have drifted to the depth of ploughing is that they should be cultivated to a very shallow depth as soon after an autumn rain as is possible. If no heavy-tined cultivator is available to do the job, the plough can be used, but on no account should it be allowed to enter the land to a greater depth than 1 $\frac{1}{2}$  in. When stirred so as to loosen only enough soil to properly cover the seed, it is not unusual to get really big crops from drifted patches, whereas, if stirred deeply, unmellowed soil is brought to the surface and produces poor crops.

**Sodium Chloride, Effect on Cattle.**

*After spraying sodium chloride on blackberries will it have any injurious effect on cattle if they ate same?* Reply—Sodium chloride or common salt would probably kill blackberries if sufficient were used, but it would require such an enormous quantity that the expense would not be warranted. The land would be rendered sterile for some years, but stock would benefit because of the salt. Sodium chlorate, which will kill blackberries when applied as a spray, leads to temporary sterility of the soil, and if good rains are experienced soon after treatment, the soil becomes fit for cropping a few weeks after having been saturated with the chlorate. The small amount present will not injure livestock, although they lick it up greedily.

**HORTICULTURAL INQUIRIES.**

---

[Replies supplied by Mr. GEO. QUINN, Chief Horticultural Instructor.]

---

**Explosives for Subsoiling.**

*What experience has the Department of Agriculture had in the use of explosives for subsoiling?* Wirrabara Agricultural Bureau). Reply—Prior to the outbreak of the great war this subject came much to the fore. I have witnessed the use of explosives in a few places—principally in the Adelaide Hills—at Norton Summit, where an old orchard of stunted apple trees was treated, and at Wirrabara prior to planting a new orchard. In the old orchard, four holes were driven to a depth of about 30 in. into the soil.

regular intervals around a tree at a distance of 5ft. from the trunk. In each of these one-half a plug of gelignite was exploded simultaneously. The result was to shake the ground in four overlapping circles, and at the simultaneous discharge the tree appeared to perceptibly lift and settle again. A number of holes were opened up to note the results, and in each case about 1ft. below the surface a cavern about large enough to hold a household bucket was found. This work was done in the autumn when the subsoil, which was of a friable clay with a few loose slaty stones in it, was in a crumbly, dry condition. Cracks extended 1ft. or so around the hole. In some instances, powdery lime was tamped over the charges and an effort made to ascertain if the explosion forced it through the soil. No evidence, however, was adducible from the experiment, which had for its object the possible distribution of fertilisers through the subsoil by such procedure. The old trees were pruned back well, and the hitherto poorly tilled orchard was submitted to good average tillage. The old trees made a good recovery during the two succeeding years, but how much was due to the loosening of the subsoil and fracturing of the root system by the explosives I am unable to say.

The work, preparatory to planting, done at Wirrabara extended over a considerable acreage of land afterwards set to a mixed plantation of stone and pip fruit trees by Mr. H. H. Jericho. These young trees made fine growth for some years after planting, but how they have stood up since through the dry seasons I cannot say. The block is, I think, near Mr. Marner's orchard. In this instance, the procedure was to explode half a plug of gelignite in each position for a tree and at a depth of about 2ft. 6in. below the surface. The exploded spot was barred down to fill in the cavity which formed in the somewhat wetter soil below, and a hole opened above it for the insertion of the tree. Mr. Jericho assured me that each hole cost about 4d. to explode and bar and open ready for the tree, but it is doubtful if that could be done at the present cost of materials and labor.

The opinion I formed from these two widely different experiments was that for an old root-bound orchard, explosives would prove an effective and probably safer substitute for subsoiling by mechanical means. In the case of new land, in the absence of large subterranean roots or solid stone strata, I do not think it could compare with the work done by a powerful caterpillar tractor and very strong subsoiler as made for use with the tractor. Land subsoiled with these implements and cross-subsoiled every 2ft. or 3ft. to break any barriers or ridges makes a much more thorough job than explosives, unless they be used at very close intervals and very great expense. The best job is made when subsoiling by either method if it is done in autumn after the first soaking rain wets the first foot of the land and only slightly damps the lower strata.

#### **Transplanting Mature Fruit Trees.**

*What is the best plan to adopt to transplant an eight year old pear tree?* (Jamestown Agricultural Branch). Reply—An eight-year pear tree may be removed quite safely under suitable climatic conditions, but it is a very risky proposition in hot, dry, and wind-exposed localities. Unless immediate removal is contemplated, the best method to adopt with an established fruit tree is to dig a trench around the tree a couple of feet from the trunk and deep enough to sever all large roots. At the same time, cut the tree back almost on to its main arms. Fill the trench with rich soil or soil enriched with plenty of old rotted manure; tramp fairly firmly and soak with water. This work should be done about the end of March. During next season the tree should be watered well and encouraged to grow throughout the summer. Next March, if the ground be opened up outside the previous trench, it will be found that the enriched soil has become filled with fibrous roots, which, if well moistened, will hold much of the soil in a ball to be carried with the tree. A good plan in lifting the tree is to split a strong sack down one side and end, and then, when excavating beneath the ball of roots, gradually work this under it. If a heavy ball is secured, a man grasps each

corner of the sack and the tree is carried bodily to its prepared position, which should be a hole larger and deeper than the ball. The sack is buried where it lies beneath the ball, the hole being filled with enriched soil, and the whole trodden firmly and afterwards soaked with water. A screen of bagging or boughs stretched on stakes a couple of feet above the top of the tree affords considerable help in enabling it to recover and progress through the first year after the removal. Old stone fruit trees, as a rule, do not stand removal so well as apples, pears, quinces, figs, oranges, and lemons. A less satisfactory method is to excavate the tree, saving most of the larger roots for several feet in length. The top is cut back as severely as in the previous method. The best time to move established trees is in the autumn or very early winter whilst the soil is warm. It is always desirable to tramp the enriched soil well down over the roots and settle the ground with a thorough soaking. In all but the coolest districts, the transplanted tree should be shaded throughout the first summer and protected against drying winds whether cold or hot.

#### Kopi for Tomato Plants.

“J. H.,” Poochera, asks whether *Kopi* is suitable for growing tomatoes and how to apply it? Reply—This is not a plant food, but is very useful in the fine form for flocculating stiff clay soils and making them more friable. Only in liberating natural potash, and in this way, could it prove beneficial to tomatoes and other garden crops. Lime compounds are usually spread on top of the roughened surface and lightly harrowed or raked in. Early in winter is the best time to do this, so that the rain may set on the land and distribute the lime between the soil particles. From about one to five tons per acre may be safely used on stiff garden land.

#### Cabbage Blight and Aphis.

What is an effective remedy for blight in cabbages; also a cure for aphis? (Kelly Agricultural Bureau). Reply—The term “blight” amongst gardeners is generally applied to the cabbage aphis. If that is meant in this case, the remedy quoted below would answer the latter part of the query also. Aphides are usually killed by contact sprays such as oil emulsions, nicotine and soap compounds, resin or starch solutions, all of which act upon the skin or stop up the breathing pores of the pest. Nicotine dusts are also destructive when containing not less than 3 per cent. of nicotine. Probably the best spray is made from nicotine sulphate (Black Leaf 40 is a popular form) which is used at the rate of 1 pint in 80 pints of soapy water. It is very important to strike the individual insects with the sprays or dusts and not apply them at random to the plants.

## WILLS AND EXECUTORS.

WHY YOU SHOULD APPOINT THIS COMPANY AS YOUR EXECUTOR.

1. It is EXPERIENCED and EFFICIENT.
2. It affords SECURITY against LOSS.
3. It is always ACCESSIBLE.
4. Its Existence is PERPETUAL.
5. It is FREE FROM FAMILY INFLUENCES.

## DAIRYING INQUIRIES.

[Reply supplied by Mr. H. B. BARLOW, Chief Dairy Instructor.]

### Feeding Cows and Pigs.

*I have liberal stocks of wheat, barley, and oats on hand. Will you advise the best method to adopt to feed the grain to cows and pigs?* "J. M. G.," Goolwa. Reply—For a cow giving about 3galls. of milk per day a ration consisting of 3lbs. oats, 3lbs. barley, and 2lbs. linseed meal will give good results. Make a mixture up of six parts oats and barley mixed and two parts linseed meal and feed this mixture at the rate of 1lb. of the mixture to each 4lbs. of milk the cow produces per day. Grind the barley for the pigs and feed it dry. If skim milk is available for the pigs, they will do well on a ration of wheat five parts, barley two parts, and oats two parts, or, if the oats are kept for the cows, feed five parts wheat and three parts barley, crushed and fed dry. Give all skim milk available. Oats are of advantage to brood sows. It will be found most economical to feed as much grain as the pigs will eat readily. Self-feeders will be found most satisfactory in the long run.

## POULTRY INQUIRIES.

[Replies supplied by Mr. C. F. ANDERSON, Government Poultry Expert.]

### Chicken Pox.

*The Secretary, Shoal Bay Agricultural Bureau, reports blotches on heads of birds which gradually spread into one large scabby swelling. The mouth is ulcerated, and the birds are badly scoured.* Reply—The disease is chicken pox which has spread to roup. Birds which are badly infected in the mouth should be killed and carcasses burnt. A simple remedy is to paint the affected parts with iodine—three applications should be sufficient—or ordinary washing blue can be rubbed on the affected parts. Spray all roosting quarters once a week with a 10 per cent. solution of kerosene emulsion, and feed Epsom salts at the rate of 1oz. per 20 birds in a mash once a week.

### Round Worms.

*A. E. W., Waikerie, reports—I am losing a number of chickens when they reach the age of three months. The birds are continually straining their necks and opening their beaks as if gasping for breath.* Reply—The complaint appears to be round worms. The fact of the birds stretching their necks is an indication of worms. It will also be noticed that the droppings are of a yellow color. Treatment—Either feed chopped onions at the rate of 7lbs. per 100 birds once a week, or mix 1 tablespoonful of turpentine to four of olive oil for each 20 adult birds, and add to the mash, or obtain Nema worm capsules from any poultry supply store and use as directed.

## VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

*"G. L. T.," Brentwood, has mare 11 years old "gone down" twice since Christmas and evidently with severe colic pains.* Reply—The trouble with the mare appears to be chronic indigestion and this is due most probably to either bad teeth or to over- or perhaps a combination of both. The following treatment is suggested:—mal's teeth attended to; starve her for 16 to 24 hours and give the following: New linseed oil 1½ pints, turpentine four tablespoonfuls; keep on bran

mashes for three or four days afterwards, and if a good purging does not result, repeat the doses of oil and turps. Subsequently limit the feeding of the mare somewhat and give one tablespoonful of *liquor arsenicalis* (Fowler's solution) in the feed night and morning for a fortnight. If a little green feed could be included in the daily ration it would be beneficial.

"L. J. M.," *Delamere*, asks what is the correct amount of *Spanish fly* to give to a lazy ram? Reply—The use of drugs such as "*Spanish fly*," &c., is not recommended as it is doubtful if they will effect the desired result, and it is quite likely that they may produce permanent harmful results if not used with the greatest caution. It is far more satisfactory to stimulate the rams by hand feeding them on a ration of oats, barley, or other grain. If their indolence is due to their being over fat, their condition will require to be reduced gradually without weakening them. An ounce of Epsom salts in warm water as a drench once a week, with judicious curtailing of their feeding for three or four weeks, will serve to reduce them to a more satisfactory condition for mating.

"A. E. S.," *Mount Cooper*, has cow, udder swollen and inflamed and difficult to milk. Reply—The cow is suffering from *mammitis* or inflammation of the udder. The following treatment is advised:—Foment affected quarter two to three times daily. After each fomentation, dry and massage gently with warm camphorated or olive oil. Strip out as often as possible during day. Isolate cow and milk strippings into a tin containing disinfectant. If no response to treatment in a reasonable time, dry affected quarter off, or if more than one quarter is affected, sell cow for beef. If milk from other quarters is normal, it can be used.

"C. J. W.," *Port Lincoln*, asks can bones of a fox poisoned by strychnine 12 months previously poison a dog? Reply—Strychnine poisoning is a rapid poisoning. In fatal cases, the strychnine is found mainly in the blood, liver, and kidneys. It is not considered that the bones, especially after a period of 12 months during which time they would be exposed to considerable weather changes, would be fatal to a dog.

~~~~~  
THE ADELAIDE CHEMICAL & FERTILIZER CO. LTD.

"E. H. P.," *Rockleigh*, reports (1) ewes close to lambing showing signs of stomach worms, (2) treatment for cow with cow pox. Replies—(1) Ewes can be dosed for worms a month before lambing. Handle carefully and dose in the standing position. Copper sulphate solution is recommended. (2) The local signs of "cow pox" are as follows:—The udder and teats become inflamed and the latter are swollen. A pale red eruption appears irregularly distributed on skin of part. In a few days blister-like vesicles form, circular or oval in shape. These vesicles are surrounded by a red inflamed zone. In about 10 days they turn into pustules which are followed by scabs. Milkers' hands and arms may become infected. Treatment consists in washing area with a weak solution of lysol, and subsequently dressing with boracic acid ointment. Affected cows should be milked last and isolated if possible. Milkers' hands should be washed.

"K. H. D.," *Black Springs*, reports cow with swelling at back and both sides of jaws. Reply—If swelling is firm it is suggested that it be fomented daily and painted with strong tinct. iodine. In the event of its breaking, syringe out with iodine. If swelling is soft and flabby, it is probably due to the poor condition of animal. In this case a purgative drench of Epsom salts should be given and cow subsequently fed on good quality feed, including bran.

"W. L. E.," *Ceduna*, reports death of cows. Post mortem showed a number of bones and nails in the first stomach. Reply—The post-mortem finding shows that the cows must have been "bone chewers," and this habit is frequently the cause of a disease known as botulism. This disease is really a poisoning, and cows usually obtain the poison from old bones or rotting carcasses. Bone chewing is an attempt on the part of the animal to obtain the mineral matter which is lacking, especially during the dry period of the year, in their feed. Treatment of cases of botulism is not satisfactory, and consists briefly in giving (1) a purgative drench of Epsom salts, (2) powdered nux vomica (a teaspoonful night and morning for 10 to 14 days), (3) the addition of mineral matter to the ration. Prevention is more important, and can be satisfactorily carried out by—(1) Collecting all old bones and burning or burying them deeply. (2) Supplying a mineral ration free from the poison of botulism. The following mixture is recommended:—Finely-ground Nauru or Ocean Island rock phosphate, 1 part; coarse salt, 1 part. The mixture can be mixed in the damped feed of cows which are being hand fed. A handful three times weekly is suggested. For dry and young stock put in troughs near watering place. It is suggested that in this case a little crushed oats and linseed meal be added to make the mixture more palatable.

Bloat in Sheep and Cattle.

"Bloat in sheep and cattle," said Mr. A. H. Robin, B.V.Sc. (Stock and Brands Department), at the Wirrabara Conference, "could be traced to a number of causes—such as eating indigestible feed, overfeeding, sudden changes of feed—especially from dry to green feed—and turning stock in hungry condition in to graze on wet grass, especially clovers and lucerne. Prevention of the trouble lies in avoiding the above causes. In cases which were not particularly severe—where the animal could still breathe with the mouth closed, relief could usually be obtained by medicinal measures alone. Rounding the animals up and driving them would often relieve the symptoms. In cows, a piece of rope smeared with grease or tar placed in the animal's mouth would often result in the gas being expelled from the paunch. Cattle could be given $\frac{1}{2}$ lb. soda in a drench—sheep up to $\frac{1}{4}$ lb. A teaspoonful of dry mustard on the back of the tongue was a useful remedy in sheep. The most efficient remedy of all, if it was obtainable, was to give cattle 8 teaspoonfuls of turpentine and 1 to 2 tablespoonfuls of cloudy ammonia in a pint of milk. Sheep could be given up to 4 tablespoonfuls of turpentine and $\frac{1}{2}$ to 1 tablespoonful cloudy ammonia.

"In severe cases it was necessary to puncture the left flank at a point equidistant from the point of the hip, the last rib, and the backbone. If no trocar was available, a pocketknife could be used. When the knife had been inserted it should be turned

edgeways, and a piece of cork or wood placed in the puncture to hold the lips of the wound apart and allow the gases to escape from the paunch. The drench of turps and ammonia could then be given to prevent further fermentation of the food.'

Licks for Stock.

Replying to a question as to a cheap and suitable lick for stock in the Lower South-East, Mr. A. H. Robin, B.V.Sc., of the Stock and Brands Department, said the Council for Scientific and Industrial Research, which controls the experimental work at Dismal Swamp, recommends the following lick:—Salt, 40 parts; dicalcic phosphate, 60 parts. If desired, about 10 per cent. molasses can be incorporated in this mixture. The cost of the dicalcic phosphate is 15s. per cwt., or £15 per ton, f.o.b., Adelaide.

Lung Worms in Sheep.

The following remedy for lung worms in sheep, a subject which was discussed at the South-Eastern Bureau Conference, was advised by Mr. A. H. Robin, B.V.Sc., of the Stock and Brands Department.

The most prominent symptom is an irritating paroxysmal cough, accompanied by a frothy discharge from the nostrils, this discharge often being bloodstained, due to haemorrhage from the lungs. Usually a number of animals in the flock are affected at the same time.

If the sheep are badly infested, they further fall away in condition, even though they continue to feed well, and become anaemic and unthrifty. Death may ultimately result from exhaustion due to the increasing poverty of condition, or the sheep may die suddenly from suffocation, due to accumulated masses of lung worms and mucus blocking up the air tubules of the lungs.

Where the sheep are infested with the smaller variety of lung worms, which lodges more in the lung tissue, the symptoms of bronchitis (i.e., the coughing and frothy discharge) may be less pronounced, but the animals may develop symptoms of pneumonia.

The only method of treatment that is to any extent successful in removing the worms out of the bronchi or larger air tubes is the intratracheal injection of certain drugs. However, these injections require skill, and entail a good deal of trouble in their administration, and are not without danger to the sheep; consequently they should only be attempted by a veterinarian. This, of course, at once limits their application to small flocks, and where the worth of the animals affected warrants the expense of getting the necessary veterinary assistance.

Lung worms are, however, seldom found alone in sheep, but are usually accompanied by stomach and intestinal worms, so that the flock should be subjected to the regular monthly treatment with either Bluestone or Carbon Tetrachloride, as prescribed for these parasites. By removing them, the sheep will have only the one enemy (viz., the lung worm) to contend with, and will usually do better and improve in condition, so that losses are minimised. Of the two treatments mentioned, probably the Carbon Tetrachloride treatment will be found to be somewhat the more efficacious. The affected sheep should, of course, receive a plentiful supply of nutritious food, so that their bodily resistance to the ill effects of the lung worm may be increased.

Generally speaking, the only efficacious method of combating the lung worm in flocks lies in prevention, and the precautions that have been advised repeatedly from time to time with respect to the combating of stomach worms apply with equal force in respect to the lung worm, which, like the other, is picked up by the sheep in their feed and drinking water. Overstocking of pastures should be avoided, pasture rotation should be practised to the greatest possible extent, and the sheep should be given a clean water supply, free from possibility of contamination with worm eggs and larvae.

Special care should be taken with young sheep, as they are more likely to suffer ill effects than more mature animals if they become infested.

Newly purchased sheep, that are likely to be clean at time of purchase, should not be allowed to depasture on paddocks recently occupied by lung worm infested sheep.

HANDLING OF CITRUS FRUIT FOR EXPORT.

The Citrus Preservation Committee of the Council for Scientific and Industrial Research recently drew up recommendations for the procedure to be followed in the handling of citrus fruit for export. This work of the Committee was carried out on the understanding that in the near future the production of citrus fruit in Australia would be much greater than local requirements and that efforts were being made to build up an export trade on a large scale.

The recommendations embodied the results of the experimental work of the Committee and of the experience of its members. As the Committee was made up of members who were concerned with the growing, transport, and marketing of oranges, as well as of scientific workers, every aspect was taken into consideration in view of the necessity for the fruit being in a satisfactory condition if the export trade was to be a success.

The recommendations were as follows:—

A. Regulations affecting Export.—All fruit must comply with the regulations under the Acts dealing with the overseas export of fruit and in particular those relating to the control of the quality and the grading of the fruit, the type of case, and the markings on the case.

B. Type of Fruit.—In view of the fact that the regulations set out in detail the type of fruit permitted for export, there is not much that can be added under this heading. It is only necessary to emphasise that only first quality fruit should be sent. The harmful effect on the trade would be very great if sour or immature oranges were included.

C. Methods of Handling in Groves.—During all operations it is most important to avoid injury to the rind. All experiments have definitely pointed to the necessity for great care in the handling of the fruit. Considerable loss is produced by mould infection following damage to the rind, and this damage can be prevented by careful handling in the following manner:—

- (1) Gloves should be worn during all operations of harvesting, grading, and packing.
- (2) Under no circumstances should the fruit be pulled from the tree.
- (3) Blunt-nosed clippers should be used, and in the actual cutting of the fruit the greatest care must be taken that no protruding stalk be left. It may be necessary to make a second cut in order to remove any superfluous wood.
- (4) No fruit resting on the ground or hanging within a foot from the ground should be used for export.
- (5) The fruit should not be harvested in damp weather.
- (6) Picking bags are not recommended as the ideal receptacle, because in a bag oranges are liable to be rubbed together and the rind bruised by the movements of the packers. It is strongly recommended that growers make an effort to provide the pickers with a box of the capacity of half a bushel; the box should be well padded inside and have straps for hanging across the shoulder.
- (7) Care should be taken to see that the fruit is not dropped, but transferred from one receptacle to another with the same care as would be given to eggs. If any orange is accidentally dropped or mishandled in any way during the operation, it should be immediately rejected, as otherwise it may be the means of ruining a whole case of fruit.
- (8) The most suitable type of field box is the box used in the canning industry, namely, a kerosine case cut open on one side with cleats nailed to each end for ease of handling.
- (9) Care should be taken to see that the field boxes have no inner surface projections of any kind; there should be no nails, protrusions of wood, or sharp knot holes, all of which are liable to cause injury to the rind.

- (10) If the weather is dry and warm, sweating in a well ventilated shed is recommended for a period of up to seven days. Under moist conditions, however, sweating will be quite ineffective and therefore is not advised unless some chamber in which atmospheric conditions can be controlled is available.
- (11) In transporting the fruit from the grove to the shed, care should be taken to pack the boxes squarely on top of each other, and the truck should be driven carefully so as to minimise the shaking as much as possible.

1. Packing House Methods.—The importance of scrupulous cleanliness in the packing sheds and of all parts of the machinery used cannot be over emphasised. To ensure this, the following precautions should be taken:—

- (1) Old fruit should not be left lying about. All mouldy or damaged fruit should be removed from the shed and destroyed.
- (2) The grading machine should be sprayed daily with a formalin solution of 1 part of 40 per cent. commercial formalin to 20 parts of water.
- (3) Where practicable, the whole of the shed should be sprayed at intervals with this solution. The floor in the vicinity of the packing operations should always be regularly sprayed.
- (4) Gloves should be worn during all sorting, grading, and packing.
- (5) It is important that the grading machine should be free from all rough, sharp edges or projections or surfaces which might injure the fruit.
- (6) It is essential that the fruit should be carefully culled and that any which shows marked signs of blemish should be rejected. Off-type fruit should be rigorously excluded.
- (7) Dirty fruit should under no circumstances be exported. Cleaning may necessitate washing and polishing, and unless the proper facilities exist for efficient washing and quick drying of the fruit, washing should not be attempted and all dirty fruit should be discarded. Where proper facilities for washing exist, the sodium bicarbonate treatment is recommended, as it is beneficial for reducing the decay due to moulds. This consists in immersing the fruit in 5 per cent. sodium bicarbonate for eight minutes at temperatures of 112° to 120° F. and drying on towel dryers. For efficient drying after this treatment, loose towels should be placed on the fruit as it passes over the revolving towel dryer. The revolving towel soon becomes so wet that it does not dry the fruit, but merely removes the excess of moisture. If dry towels be tacked on the machine so that they rest loosely on the fruit the efficiency of the apparatus is increased enormously and the fruit can be actually dried. These loose towels, which should be made to fit the machine, need to be changed and dried as soon as the condition of the fruit points to the necessity.

Design No. 11.

SEND FOR CATALOGUE.

TIMBER

FOR EVERY JOB.

TERMS ARRANGED.

COWELL BROS. & COY. LTD.,
ADELAIDE, NORWOOD (Head Office), and PORT ADELAIDE.

- (8) Only export citrus cases (23 x 11½ x 11½ inside measurements clear of a division) should be used. The space between the side boards must not be more than ¼ in. Each case should be dressed particularly on the inside and be free from projecting nails, loose splinters, or anything that might injure the fruit.
- (9) In packing, great care should be taken to see that the fruit is to the correct height in the case in order that "lidding" can be carried out without damage to the fruit. The use of box guards on the middle division piece and round the inside is recommended during "lidding" in order to prevent injury.
- (10) The experiments of the Committee have not as yet gone far enough to recommend a definite method of wrapping. It is considered, however, that wrapping in an attractive paper is advisable, in that it enhances the selling qualities very considerably.

E. Transport by Rail.—The cases should be carefully packed in a railway truck in such a way that undue movement is prevented. They should be stacked on end, and for preference should be battened, but if battening is impracticable the cases should be stacked in such a way as to prevent as much movement as possible. Cleanliness in the trucks is as essential as in the packing shed.

F. Pre-cooling.—Broadly speaking, all fruit consists of living matter and materials which have been stored up in the fruit during the period of growth on the tree. After the removal of the fruit from the tree, the living matter is dependent for its maintenance upon the materials stored up, and when these are used up the fruit dies. The life of the orange, therefore, is limited, depending upon the quality of stored material and on the rate at which this material is used up.

The vital activity of the fruit depends upon its temperature, increasing with rise of temperature at an accelerated rate, and the object of storage at a low temperature is to reduce its rate of living and so prolong the life of the fruit. This using up of stored material is accompanied by actual production of a proportional quantity of heat, and so if the fruit be loaded hot into the ship's hold, the refrigeration machinery has to remove not only the heat already in the fruit, but also heat which is constantly being produced. It may, therefore, be some time after loading before the temperature at which it is desired to carry the fruit is attained throughout the stack. This means that the life of much of this fruit is shortened.

All fruit should therefore be pre-cooled to 40° F. before being loaded into the ship, since pre-cooling lowers the rate of living and thereby lengthens its life. As oranges have only a limited life, it follows that all time taken up after picking, sweating, packing, &c., is so much time taken off the storage life of the fruit, which really starts when the fruit is removed from the tree. It is, therefore, essential that the fruit should reach the pre-cooler as soon as possible after picking, so that the vital activity, and therefore the reduction of its stored material, is reduced to a minimum.

G. Ship Transport Conditions.—The temperature of storage on the ship should be 38°, and the holds should be subject to periodical ventilation.

General Instructions.—It has already been stated that the life of the fruit from the time it leaves the tree is strictly limited, and any unnecessary delay between the time of harvesting and the time of sale means a shorter time during which it will be in good marketable condition.

It is, of course, manifestly impossible to make arrangements for a shipment of any size without at least some of the fruit having been harvested earlier than the rest. As, however, the process of decay is very much slower when once the fruit is in cool storage, it is essential that the actual processes of harvesting, washing, packing, and transport to the cool stores must be managed as expeditiously as possible. If the fruit must be held for some time before shipment, it should be held in cool store and in the packing shed.

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR APRIL.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

The special work of the month should be an attempt to control plant pests, both insect and fungous. Codlin moth may be considerably lessened by destroying all wind-fall fruits, by boiling them for pig feed, or by burying them deeply; this procedure will also tend to destroy much of the fungus spores adhering to the fruit. Use bandages about the trees which were infested by codlin moth and examine them within the next month or two, destroying the contents, and storing the bandages for future use. Spray all trees subject to fungous diseases either with lime-sulphur or Bordeaux mixture, and at the same time direct the spray on the fallen foliage.

When filling blanks in the orchard, dig the holes, and provide fresh soil for the young tree. For new plantings, the holes should be ready to receive the trees at the earliest opportunity.

Pruning may be commenced so soon as the foliage has finished its work; in any case remove dead limbs, clean the cuts, and paint with thick white paint or white lead. The dead cuttings should be collected at once and burned. Vine pruning may also be started where the foliage is done.

As soon as the harvesting is complete clean all the picking outfit and boxes and repair where necessary, then store away until next season; all the drying outfit should be treated similarly.

Protect young citrus trees from possible frosts or extreme cold by wrapping hessian or paper about the stems, and keep the soil loose.

Get cover crops in at earliest moment, manuring them with super or bonedust, and use a little potash about trees which have shown a tendency to "scorch"; $\frac{1}{2}$ lb. to 1 lb. per tree will be sufficient, ploughed in when putting in the crop, or dug in.

See that surface drains are in order and arrange to prevent washaways if possible. Outlets of underdrains must be kept free, to keep them from silting.

Hoe strawberry beds, and make sure that water will not lie about the plants.

Have ploughs and other implements for cultivating in readiness for use.

THE ORIGIN AND HISTORY OF THE CLEOPATRA APPLE.

[By GEO. QUINN, Chief Horticultural Instructor.]

Although this apple holds a prominent position amongst the varieties grown for export and home consumption in all of the apple-growing States of the Commonwealth, its origin has been largely treated as a matter for conjecture amongst pomological students and nurserymen in Australia.

CLEOPATRA APPLE from South Australia (natural size).

Judging from the aged trees found in the apple-growing States, it has probably been grown here under various names from a period extending back into the middle of last century. In Tasmania it has been known as the New York Pippin, and in this State

—more than half a century ago—it was marketed as Pomeroy, but the origin of the present name of Cleopatra appears to be as uncertain as the origin of the variety itself. Although the name of Cleopatra was adopted by the now defunct Pomological Committee of Australia, which achieved a good work in unravelling the nomenclature of many of our apples and pears, that body did not attempt to trace out the origin

ORTLEY APPLE from Oregon, U.S.A. ($\frac{1}{2}$ natural size).

and history of this apple. It is true brief references may be found in catalogues, or statements made by nurserymen and horticultural writers of 50 years ago asserting or hinting that the variety was a synonym of the American apple called Ortley, but if they were in a position so to do, they produced no convincing evidence substantiating that contention.

In the "Fruit World of Australasia" for August, 1929, on page 289, a Mr. L. C. Tonkin, of Otago, New Zealand, referred to the Ortley apple grown in the north-western States of America as being synonymous with "our Cleopatra." This reference came under the notice of Mr. H. P. Gould, Senior Pomologist in the Bureau of Plant Industry, at Washington, U.S.A., with whom I had previously held correspondence relative to the nomenclature of fruits. Writing in October, 1929, Mr. Gould asked if I could throw any light on the origin and history of the apple grown in Australia and New Zealand under the name of Cleopatra, as that name was not known in American pomology, and considerable doubt was still attachable to the synonymy indicated by Mr. Tonkin. He expressed the opinion that the point could only be permanently and definitely settled by critical comparisons of authentic specimens of the fruits being made side by side.

In acknowledging Mr. Gould's courteous inquiry, it was suggested he endeavor to procure and cold store typical specimens of the Ortley fruits grown in the United States of America, and we would dispatch specimens of our Cleopatra fruits to Washington as soon as they were sufficiently developed to mature on the journey. This course was followed, and in April, 1930, two small parcels, containing fruits of Cleopatra displaying the variable shapes and sizes it assumes in this State, were dispatched. These, with one exception, came into Mr. Gould's possession in an excellent state of preservation on May 22nd following. They were critically examined by the scientific staff of the pomological division of the Bureau of Plant Industry, who, after minute dissections were made, unanimously declared them to be identical, in their opinion, in every particular with the fruits of the Ortley, which had been stored for the purposes of comparison.

Paintings in water color were made, both of the South Australian and American specimens, and photographic reproductions developed therefrom. At the same time, technical descriptions of the structural characteristics of the fruits were compiled.

Through the courtesy of Mr. Gould, specimens of these prints, together with copies of his technical notes, have reached this office, and proved a source of much interest to many local growers of the Cleopatra apple. From these pictures one of a fruit from each country displaying an apple in general elevation, and in longitudinal section is shown herein, and the resemblance is very closely defined. At the same time, Mr. Gould sent along a copy of a contribution he was making on the subject to the "Better Fruit" magazine and to "Fruits and Gardens"—the latter being the official organ of the American Pomological Society. These studies into pomological nomenclature and synonym were printed in "Better Fruit" for October, 1930.

Finally, in keeping with an earlier promise, Mr. Gould dispatched in December last a box containing three specimen apples of the Ortley as grown in the famous Hood River Valley, in Oregon, and four others obtained from the New York Experiment Station Orchard, at Ithaca, New York. These arrived in Adelaide in a splendid state of preservation early in February, 1931. The fruits from these widely separated districts in the United States of America externally presented those differing characteristics which can be observed between the Cleopatra when grown in Tasmania and when produced in the warmer parts of this State. They have been shown to a great number of our principal growers of the Cleopatra and students of pomology from various districts of this State, who, without being informed of their origin, have, without exception, pronounced them to be identical with our Cleopatra apples.

Some of the specimens have been dissected and tasted in this office, and, allowing for differences due to condition, I am thoroughly convinced our well-known Cleopatra is none other than the same variety which is recorded in pomological literature as having originated in the orchard of Michael Ortley, in Southern New Jersey, U.S.A., and was first described in America by Coxe, in 1817, under the name of Woolman's Long Pippin, and which was sent to the Royal Horticultural Society of England by a pomologist named Floy in 1825 under the name of Ortley. W. H. Ragan, of the Bureau of Plant

Industry, at Washington, U.S.A., in his comprehensive catalogue of varieties referred to in American publications from 1804 to 1904, entitled "Nomenclature of the Apple," cites some 30 synonyms for this variety in America. Mr. Gould advises me it is widely scattered through the United States of America, but commercially grown in the north-western States only. Nowhere is it placed in the group of leading varieties.

In describing the characteristics of the Cleopatra tree in this correspondence, reference was made by me to the susceptibility of its fruits to the Bitter Pit or Baldwin Spot when grown in certain of our districts. In commenting on this Mr. Gould wrote, "I am surprised to know that this variety is susceptible to Bitter Pit or Baldwin Spot, as the disease is commonly known in this country. I am, however, not aware that it is not noticeable in sections of this country where it is grown."

3 Harrows in One for the Price of One

The Whakatane Harrow is an all-purpose implement designed in such a way that three exceedingly efficient working surfaces can be secured from the one set of harrows. On the one side a long time cultivation is provided for, on the other, when drawn one way, the harrow becomes a first-class tripod, and when drawn the other way, as shown in the accompanying illustrations, a manure-spreading, seed-covering harrow, which many skilled farmers and agricultural experts claim as being the finest manure spreading effect so far made possible with harrows. The Whakatane is designed to treat all classes of country and to suit different types of farming—wheat areas, dairying and mixed farming—being particularly suited for the renovating of pastures and the preparation of seed beds. Its principle of "three harrows in one" gives it an extremely wide scope of usefulness and renders it superior to any of its kind.

CONFERENCE OF SOUTH-EASTERN BRANCHES.

The following papers were read by members of South-Eastern Branches of the Agricultural Bureau at the Conference held at Kalangadoo on March 18th:—

ENSILAGE AND GRASSLAND MANAGEMENT.

[By R. J. CLEVE, Mount Gambier.]

In submitting this paper to Conference, I wish to impress upon farmers the advantages that have resulted from grassland management to the dairy farmers of New Zealand. The intensive system wherever it has been adopted has almost doubled production, and is rapidly gaining favor in other dairying lands throughout the world. By this means land which would otherwise have been non-productive has been utilised to its full productive capacity. The fundamental and essential basis of grassland farming is rotational grazing. The next, and certainly the most influential factor, is the use of fertilisers, but no matter how liberally applied, it will never be used with any great amount of success unless the increased growth or herbage is effectively controlled. The only method in which this can be accomplished is by the new system of rotational grazing. In New Zealand, where this system has been extensively practised, the four main processes used in operation are:—1. Subdividing of paddocks. 2. Making of ensilage. 3. More complete harrowing. 4. Top-dressing..

The subdividing of paddocks into smaller acreage has a distinct advantage inasmuch as it makes for easier working and more complete control. Heavy stocking—being one of the phases of rotational grazing—the pastures are consequently more evenly eaten down (a very important point), than would be the case in paddocks containing 10 to 20 acres. In paddocks of this size, much loss in feed is occasioned by cows grazing on sweeter and neglecting the ranker patches of pasture, especially where droppings have accumulated and have not been spread by harrowing.

Under the new system of grassland management, the average area of paddocks is from 4 to 6 acres. These paddocks are top-dressed in the spring with an average of 3cwts. to 4cwts. of fertiliser to the acre. This again is carried out in autumn, when another dressing is applied. This dressing usually consists of super, with a basic or potash percentage, and about 3cwts. of lime. It is from August to December—the flush months of feed—that the advantages of this method of control are brought out more than ever. During winter the herd is turned into the biggest paddock on the farm and fed a balanced ration of ensilage and hay. Previously, all paddocks have been top-dressed and shut up. With the approach of August and spring grasses, each cow as it comes in is turned on to a clean, fresh pasture and left until the grass is thoroughly eaten down hard, after which the herd is then moved on to the next paddock. This method is continued until the herd has rotated round all the paddocks that have been set aside for the principle of rotational grazing. By then sufficient time will have elapsed for the first paddock to have recovered its growth and the grass will once again be available for grazing. Harrowing is a very important link with rotational grazing, and each vacated paddock is thoroughly harrowed to scatter droppings after the herd has passed through. Too much harrowing cannot be practised, for it is imperative and essential to vigorous and continuous growth of plant life.

The main factor is never to allow the pasture to grow beyond the leaf stage. In paddocks which have been more liberally treated with fertiliser, it is impossible to keep the herbage down even with hard stocking. When such cases occur, the paddock is mowed and the surplus converted into ensilage.

"NO FEAR OF A DROUGHT WITH A METTERS ABOUT."

The use of sheep as followers after the cows is of vital importance to grassland farming. To maintain pastures in their most profitable condition, a number of sheep following on vacated paddocks will eat down surplus grass left by cows, and in doing so, effectively do the work of preparing for another crop of grass. Experiments have shown that where sheep have not been used as followers, the heavy harrowing and rotational system are likely to cause conditions suitable to the growth of pasture plants that are not altogether desirable.

The only serious drawback to the use of sheep is the fact of increasing the demand for food during winter, when the growth of grass is at its lowest. This can be easily overcome by making ensilage.

ENSILAGE.

The making of ensilage, another process in rotational grazing, is a most vital requirement for effective grassland management. In making ensilage it is optional as to whether a pit or a stack is used. Personal experience has taught me that a pit dug in the hillside is more suitable, for there is a minimum of waste, heat is more permanently retained, greater freedom from wind and rain, and also more liberties can be taken in filling. A great mistake is to make the pit too narrow. There is more waste in proportion than there would be in a big pit, with the result that the ensilage cools down more quickly and deteriorates. Another mistake often made is ensiling too slowly. When beginning the stack or pit, it is advisable to work on small areas, cutting only sufficient that can be stacked or pitted that day. The best plan to adopt is to cut in the morning and stack in the afternoon. No time must be lost after the grass is cut before getting it into the pit or stack. This must be well tramped and sufficient time elapse in order to generate heat. On clear fine days 24 to 36 hours are sufficient, but on cold or wet days longer times are necessary. Once heat is generated in the lower portion of the stack, no time should be lost until filling is completed. If too much spelling is indulged in—and especially if the material used is dry and overgrown—wilting and overheating will occur, with the result that the ensilage becomes overcooked. Overheating can be partially controlled if the grass is cut in the leaf stage, stacking as quickly as possible, working on small areas, and well tramping the outer layers to the exclusion of air.

When filling the pit or stack, a common mistake is to keep dumping material in the one place all the time. The majority dump it on the sides. This continual dumping in the one place will cause the grass to become more compressed on one side, causing a distinct cant. This will create an air pocket, a thing that should be avoided. When filling, it is a good plan to keep dropping the material in the centre; this will have the effect of creating a crown, and as each load is dumped, it is essential that it be well tramped, especially along the sides and ends. Insufficient pressure on top is a common fault in most ensilage pits or stacks. The greater the pressure, the better the silage. In ensilage that has been made with mature grass or *paspalum*, heavy weighting is imperative, and at least 12 in. of earth or clay is needed. In every case it pays well to weight the stack heavily.

Making ensilage from grasses in its best producing stage is nearly as good as grass itself, and in making it early means that pastures are kept in a better grazing condition than when grass is allowed to develop to the full flowering stage. Another thing in its favor is that it will not leave a hard stubble, which is generally left after a mature crop is cut, and which tends greatly to retard the following growth.

The great advantage of the small field when it comes to ensilage making is that it can be spared from the scheme of rotational grazing, and with many small fields, each can be shut up and cut in succession to give ensilage material at the right time for continuous filling. If good results are to be obtained, consideration must be given to

early closing of paddocks, so that the ensilage may be made as early as possible during the flush months of feed. This will not be only of great advantage to the quality of the ensilage, but also to the subsequent growth of the pastures.

Under the system of rotational grazing on intensively treated land, the flush months of pasture growth are usually exceptionally vigorous, and if the increased growth is allowed to come to maturity, the feed value will be greatly diminished. The fact that a moderate allowance of ensilage per day will keep a full grown sheep in good condition during winter, makes it more valuable for a minimum of cost. Sheep may be kept through winter with no interference whatever to dairy cows, and when the growth of grass is practically at its lowest.

The making of ensilage means better pasture management and eliminates the possibility of being short of fodder in winter. It also creates a control over weeds and grass which formerly had not been used for grazing. Used as the chief supplementary feed, it is rapidly ousting hay and other root crops, as the main standby until the spring grasses are available.

In the discussion which followed, Professor A. J. Perkins, Director of Agriculture, doubted whether the heavy applications of manure recommended by Mr. Cleve for pasture land would prove practicable in the South-East, excepting possibly in those districts in which the rainfall was heaviest, and in which the soil would continue sufficiently moist during the greater part of the year for the continued growth of grass. Rotational grazing was a practice more or less adopted by all graziers who subdivided their properties. Whilst he had always been a strong advocate of adequate subdivision of pastures, he felt that the question of costs placed a limit on the extent to which the South-Eastern farmer could go in this particular direction; he could not imagine that five-acre paddocks would become at all common on the average South-Eastern farms.

In recommending heavy dressings of fertilisers, Mr. Cleve had made no reference as to whether nitrogenous fertilisers were included among them. At all events, a practice of top-dressing pastures with nitrogenous fertilisers, coupled with rotational grazing, had been recommended by other interested parties. In so far as he, Professor Perkins, could see, the success of the use of these costly manures, coupled with rotational grazing, would depend very largely on the extent to which the growing period of the grass extended, and unfortunately this extension of the growing period was dependent upon the rainfall more than upon fertilisers. The South-East, quite as much as the rest of South Australia, was exposed to frequent summer droughts when the grass could not be stopped from running up to seed, and when consequently rotational grazing would come to an end comparatively early in the year. The present practice of heavy phosphatic dressings had the reverse effect inasmuch as phosphatic dressings tended to hasten the maturity of the plant and consequently to shorten the grazing period, and unfortunately experience has shown that the South-East, like the rest of the State, requires phosphates, and these tend in some measure to undo the work of nitrogenous top dressings. Hence, he believed that it would be only in those portions of the South-East where the rainfall was most regularly distributed throughout the growing period, that rotational grazing on the lines recommended by Mr. Cleve could be achieved with any degree of success.

The Director did not agree with the statement of the writer of the paper to the effect that the best quality ensilage would be made from crops in the leafy stage, which had not yet put forward their flowering stalks. In his opinion both maximum yields and optimum quality in ensilage would be secured from grasses cut just as they reached the flowering period of growth. He supported the desirability of harrowing pastures and "spelling" paddocks from time to time.

THE MARKETING SYSTEM.

[By W. LASLETT, Allandale East.]

Under our present system of distribution there is always a danger of over-production. Supply and demand, we are told, control the market in regard to wheat and wool, both of which find an outlet in the markets of the world, and in this paper I intend to deal chiefly with products that are mainly dependent on a home market, products that by closer co-operation between consumer and producer could, I feel sure, be distributed on a much better principle with benefit to both parties.

Potatoes.—The middleman, or distributor, plays a much bigger part than supply and demand with some lines. Let me deal first with potatoes. South Australia at the present rate of consumption—which, I believe, could be doubled—imports on an average two-thirds of her requirements. Therefore, there should be no fear of our production within the State, but the prices charged by the middleman or the vendor control the demand, for two-thirds of the consumers purchase potatoes by the pound. As a means of comparison, I will give the difference in our district last season of the price the producer received and the price the consumer paid. Bag lots were being delivered at 7s. per bag; the middleman was selling out at 10lbs. for a shilling, or 15s. per bag, thus netting 8s., while the farmer, who has to pay taxes, does all the labor, find bags, etc., only received 7s. That is a true comparison in a district where potatoes are grown, so assuming that only the same difference applies where potatoes are not grown, and that my estimate that two-thirds of the population buy their potatoes by the pound is correct, by basing my calculations on an average family of six, consuming 700lbs. of potatoes per year, I find that the consumers in South Australia lost annually something like £100,000—all paid to the middleman, with no gain to the producer whatever.

Fruit.—Much the same applies to the marketing of fruit, the middleman taking by far the greater share of the profit. Apples, perhaps, more so than potatoes are bought by the pound. I do not know what the producer could have got, but I know that apples sold at 4s. a case were retailed again at 2½d. per lb., a further loss to the consumer of 4s. per case. Such prices limit the demand; whereas a family of six could consume, we will say, 30 cases per year, they would, under the present system, hardly use a third of that amount. This means that two-thirds of the crop have to find a market outside the State, and, in many instances, the grower finds it a better paying proposition to let the apples fall off the trees and rot, than risk the small returns from a glutted market. Dried fruits are the same; the consumer buys a few pounds at a time, the grower loses, growls, and complains about the system, but does scarcely anything to alter it. The producer does not fix the price of the commodity, nor does he advertise the fact that he has it for sale. That part of the business is left to the agent or middleman. Prices are not fixed; the agent gives what he thinks, the consumer gives what he is asked or goes without—which is often the case. Surely there is need for closer co-operation between producer and consumer.

The Distribution of Produce.—It seems to me that the consumer needs educating in the way of buying and should purchase in bulk wherever possible direct from the producer—potatoes by the ton or bag, fruit, both fresh and dried, including currants and raisins, by the case; honey in 60lb. tins, and so on. But the grower does not advertise, and the consumer does not know where to send, or what the freight will be, and it is here that Branches of the Bureau can help one another through the medium of the *Journal of Agriculture*. We are all consumers and most of us are producers. Why not advertise what we have to sell or what we wish to buy, at our meetings. A Branch could consult its members as to their requirements in the lines mentioned. Most of us know our requirements for six months or so, and it should be possible by these means to place a fairly large order and lessen freight charges. As we read the reports of meetings we would read also the price of commodities for sale in ton, bag, or case lots

in certain centres. I would also suggest that the *Journal* publish a list of the freight charges on different articles per 100 miles by rail. We could then figure the matter out and know nearly what the cost would be. Working along lines similar to those I have set out, we would be helping one another, helping the railways, and assisting the State.

STANDARDISATION OF PRIMARY PRODUCTION.

[By B. H. RICHARDSON, Penola.]

Australia is essentially a primary producing nation, and if she is to maintain her present position, and capture fresh markets, she must pay greater attention to the standardisation of her primary products. With lower world's prices we are up against severe competition, and one of our serious drawbacks is our great distance from the markets of the old world, costly freights eating up our profits. For instance, America can land two cases of apples in Europe at the cost of one from Australia. To my mind, we have been depending too much on the markets of the Old World, and neglecting the teeming millions so close at hand.

With regard to poultry, standardisation starts with the breed. I am a great believer in the purebred. Good prices are paid for guaranteed infertile eggs, as compared with the farmer's lots. As England imports some £23,000,000 worth of eggs every year, there is thus an unlimited market for our egg production. A portion of our present wheat surplus could be disposed of in the form of eggs. The export of dressed poultry is a line which has not received the attention it deserves. The Government Produce Expert Department has every facility for treating and grading heavyweight birds, and, like egg production, there is a big market in the Motherland.

Pigs.—Pig-breeding will not pay unless everything consumed is produced on the farm. Pig production goes hand in hand with dairying. Bacon-curers are demanding standardisation, and the Tamworth-Berkshire cross seems to be an ideal pig. Too many kinds of pigs are bred, and the breeds should be narrowed down. There is, as far as I am aware, not much data as to the ideal breed, or first cross, for export purposes. In the production of bacon, greater attention should be paid to the growing of lucerne. United States of America breeders practically grow their hogs on alfalfa, topped up with corn.

Cows.—The Roseworthy Agricultural College has a particularly fine Jersey herd, and coming closer home, our Kybybolite Experimental Farm has bred a first class herd of Ayrshires. These cows are all tested, and if the average farmer's cow produced anything like the butter test of the above farms, South Australia would not need to import thousands of pounds' worth of butter every year. Here is a splendid field for exploitation. Standardisation should start with the cow on the farm, and the factories in conjunction with skilled Government Dairy Experts will do the rest. To build up a good dairy herd will take years. Like sheep-breeding, much culling must be done, before all the boarders are weeded out. The cows in this district have improved, but they have a long way to go yet. Here and there you see a very nice herd, but mostly all colors, shapes, and sizes. As far as the dairying industry is concerned, we have Dairy Experts and Instructors, but unfortunately much of their sound advice falls on barren ground. The South-East should be the home of the dairy industry in South Australia.

Sheep.—The revenue derived from this source alone has decreased by some 15 million pounds. Australia has improved her Merino flocks out of all knowledge, and judging by the local yardings, our South-East breeders are producing a fine type of sheep, carrying considerably more wool than some years back. Every breeder has a certain knowledge of wool-classing, and our wool salesmen class and lot our wool, so it may be said that in wool products standardisation has reached a high level. The South-East this year

has put up a record for the number of fat stock sent to the Adelaide markets. With the great improvement in our pastures, due to fertilising, &c., there are big possibilities in the export of fat lambs. Here standardisation comes in again in arriving at the best blackfaced crossbred lamb that can be raised in three or four months on its mother fit for export. We can with improved pastures produce nuggety lambs, and the Government Export Department will do the rest.

Fruit Industry.—With fruit, standardisation plays a big part, not only in the varieties of trees to grow, and the got-up of the fruit, &c. South Australia exported some 600,000 cases of apples to the markets of the Old World last year. Grading for size and quality is a big factor in apple production. Apples for export are now sized into eighths. For example, 2½in., 2¾in., &c., up to 3in. This is necessary for perfect packing in the new standard case. If correctly packed, for instance, every case of 2¾in. apples should contain the same number of fruit. Under the standard pack and standardisation of varieties of apples, our export trade should reach a high level. Our dried fruits are all graded by machinery, and are known as 2, 3, 4 Crown according to the sizing of the fruits, i.e., they pass through holes having certain diameters. At one time there was a big demand for dried prunes, large and small, but the trade is demanding standardisation, and a larger sized prune, going 22, 24, &c., to the pound is required.

CLOVER HAY MAKING.

[By E. C. H. SCHINCKEL, Kybybolite.]

With the advent of Subterranean clover and top-dressing, a big forward step has been made in the South-East in the development of pastures. So excessive has been the growth that to many of us it has caused considerable thought as to how it may be utilised and a great waste of valuable fodder avoided. There is no fodder plant known to the writer which provides such an abundance of highly nutritious fodder all the year round as well-cared-for Subterranean Clover, but, like all other fodder plants, it has its lean period, which in the case of this plant occurs in the late autumn and early winter, just after the rains commence.

In average seasons—from early spring to the time when the autumn and winter rains come—well established clover paddocks liberally fertilised will carry three to four sheep to the acre, and in some cases more, but after the first rains which spoil most of the dry feed, there occurs a lean period while the young plants are establishing themselves. As with all our pastures in the South-East, excess growth occurs in the spring, when usually the stock available are quite inadequate to utilise all the feed. The wise man stacks to the leanest period, but if a full complement of stock is to be carried all the year round, and the best results obtained from our pastures, supplementary feeding has to be resorted to during that lean period. With such a growth of feed during the late spring, a wonderful opportunity presents itself for storing up a quantity of highly nutritious fodder at a relatively low cost.

During the last three years the writer has been storing annually 100 to 150 tons of clover hay, by various methods. Results have been so pleasing that every hour during the limited period in which these operations can be conducted is availed of for clover hay making. Feeding results from this hay have been so pleasing that on the writer's property it has definitely taken the place of cereal hay. All classes of farm stock show a decided preference for it over any of the cereals, and it has the advantage of being produced much more cheaply. It is of higher feeding value, and can be stored indefinitely without interference from mice.

Last winter will be remembered by stockowners in the South-East as a very lean one—so far as feed was concerned—and where full complements of stock were being carried, hand-feeding had to be resorted to if stock were to be kept in good condition. With a relatively large proportion of lambing ewes in his flock, which necessitated preserving good pasture paddocks for these, the writer was compelled to resort to hand-feeding fairly extensively, and big mobs had to be concentrated in small paddocks in some cases. In one case, 700 weaners were shut in a 40-acre paddock for 12 weeks, and were fed entirely with clover hay. The writer considered this a good test for the feeding value of this hay, and the results were only to increase his enthusiasm for this fodder.

Excellent results were also obtained from topping off wethers for the Adelaide market during the winter months. Though these sheep were grazing on an abundance of luscious feed, they would always race to the motor truck that took out their daily rations of hay. It was very obvious also that sheep hardened off with this feed did not show the ill-effects of the long journey to Adelaide as sheep trucked straight from the green pasture without it. It is excellent for feeding dairy cattle, quite equal to cereal hay for working horses, and even pigs seem to relish it.

There are various implements used in the making of this hay, and the equipment necessary depends on the quantity to be handled. For small quantities the mower and horsrake are the only essential implements, the stacking being done with forks. This method is slow and tedious, and where large quantities are to be handled the sweeprake and mechanical stacker or the sweeprake and baler are advocated. As the above three methods have been employed on the writer's farm, the respective merits of each will be dealt with in the order mentioned.

As before said, with the use of the mower and ordinary horsrake to put the clover into windrows, only a limited amount can be handled unless a great deal of labor is employed; though, of course, the outlay in machinery is small. Where large quantities,

say 50 tons or more, are to be hauled, the cost of the sweeprake and stacker will soon be repaid by the saving in labor.

Mechanical stacking is the quickest and cheapest method of the three. A boy can manage the sweeprake, which picks up its load from the mower swath and deposits it on the stacker. It is then hoisted by a horse straight on to the stack, where one man is required for the building. By this method a boy and a man can stack 10 to 12 tons a day.

From the writer's experience, however, the baling process—though it involves a good deal more capital cost in machinery—has decided advantages over stacking loose. Chiefly they are these: That the hay is contained in about one-third the space required for the same quantity stacked loose, necessitating a smaller outlay in covering from weather; it is much more convenient for feeding out to stock, and is ready for market should there be any surplus for sale. The only advantage the loose stacking method has over the baling is that it is a little cheaper, but this saving is soon lost when feeding out to stock, as it involves a great deal more labor than feeding out the baled hay. At one period last winter 2,000 sheep were being hand-fed on the writer's property. These were fed in five different paddocks, and two men with a motor truck used to complete the job in an hour. If loose hay had been used, necessitating knifing out of the stack, this work would have taken two men half a day. Another disadvantage in the loose hay method is that in the event of marketing it would have to be handled again for baling. The writer is also of the opinion that the valuable feeding qualities and natural aroma are better preserved in the baled hay.

The baling process requires two men and two boys. The sweeprake picks up the hay from the mower swath and deposits it alongside the bale, where one man forks it straight into the machine. One man is required for the wiring and tying, and another lad to assist with the wiring and to stack the bales. From 10 to 12 tons can be baled in a day.

Mowing may be commenced as soon as the clover has reached its maximum growth, which usually occurs in the earlier South-Eastern districts about the end of October or early November. Heavy types of mowers are necessary to stand up to the strain in a heavy crop. The writer advocates the use of a cut of not more than 4ft., which is a very good load for two horses. Knives should be sharpened twice a day, and the machine kept in a rigid condition.

Paddocks intended for cutting may be grazed up to the middle of September or even later in the lower South-Eastern districts, and will then produce 30cwt. to 2 tons per acre of hay; provided, of course, that it has been well fertilised. Care and judgment are required in the baling and stacking of this hay. The ideal condition is to get it into bales or stack without losing the leaf of the clover, but to have it sufficiently dry or cured to prevent mould, great care must be exercised in avoiding baling or stacking when there is any external moisture such as dew or rain on the hay. This will cause mould, and if in excess, may cause combustion. Only experience can teach one his part of the business, but by close observance one can soon tell when the hay is in a nice condition for handling.

With favorable weather for curing, the hay is usually ready for stacking or baling in four to five days after cutting, though the weight of crop influences this very considerably. In a very heavy crop, where the hay lies thick in the swath, the upper portion dries out much more quickly than the lower, which sometimes takes eight to ten days to dry. To get a perfectly even curing, a tedder or swath turner is necessary, but these implements are not procurable in Australia at present. Apart from the conservation of this valuable fodder, the mowing of these paddocks has proved very effective in suppressing relatively useless weeds when cut at the right time, keeping the pasture in a fresher condition and thus preventing deterioration.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF SOUTH-EASTERN BRANCHES.

Branches of the Agricultural Bureau situated in the South-Eastern districts of the State met in Conference at Kalangadoo on March 18th. There was an excellent attendance of delegates from the Penola, Coonawarra, Allandale East, Tantanoola, Kalangadoo, Millicent, Mount Gambier, Naracoorte, Glencoe, Tatiara, and Kybybolite Branches.

The Department of Agriculture was represented by Mr. S. Shepherd (Advisory Board of Agriculture), Professor Arthur J. Perkins (Director of Agriculture), Messrs. H. B. Barlow (Chief Dairy Instructor), L. J. Cook (Manager Kybybolite Experimental Farm), E. S. Alcock, H. H. Orchard and W. H. Downes (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

Members of the Kalangadoo and surrounding Branches are to be congratulated on the very fine exhibit of produce displayed in the hall. This included dried, fresh, and preserved fruit, cereals, vegetables, tobacco plants, green fodders, and specimens of needlework tabled by members of the Kalangadoo Women's Branch.

Mr. W. J. Hemmings, President of the Local Branch, occupied the chair, and the opening address was delivered by Mr. S. Shepherd. The following papers were read and discussed:—"Ensilage and Grass Land Management," Mr. R. Cleve (Mount Gambier); "The Marketing System," Mr. W. Laslett (Allandale East); "Standardization of Primary Products," Mr. H. Richardson (Penola); "Clover Hay Making," Mr. E. Schinckel (Kybybolite). Numerous questions were answered by Departmental officers, and the following resolutions were carried:—"That the 1932 Conference be held at Bordertown"; "That it be a recommendation from this Conference that washed super bags be allowed for use as containers for potatoes and grain other than wheat"; "That in future evening sessions at Conferences be cut out, and that Free Parliament be brought on earlier after luncheon."

Certificates conferring Life Membership of the Agricultural Bureau were presented by Mr. S. Shepherd to Messrs. W. Hemming and W. J. Bennett, sen., of the Kalangadoo Branch.

After luncheon, which was provided by the members of the local Women's Branch, a special session was held for women. Mrs. W. Varcoe (Millicent) read an instructive paper, "Breadmaking."

CONFERENCE OF MID-NORTH BRANCHES.

The thirty-fifth Conference of Mid-north Branches of the Agricultural Bureau was held at Wirrabara on March 11th, 1931. There were present Messrs. A. M. Dawkins (member Advisory Board of Agriculture), Prof. A. J. Perkins (Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), A. H. Robin, B.V.Sc. (Government Veterinary Officer), C. F. Anderson (Poultry Expert), E. L. Orchard, J. B. Harris, J. O. Hatter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau), and a very good attendance of delegates from the following Branches:—Tarcowie, Wirrabara, Booleroo Centre, Laura, Yandiah, Appila, Georgetown, Caltowie, Jamestown, Eurelia, Murraytown, Morchard, Bundaleer Springs, Nelshaby, and Gladstone.

Mr. P. J. Curnow (Wirrabara) read an instructive paper, "Practical Fire Fighting," and officers of the department replied to many questions which were brought forward. It was decided to hold the 1932 Conference at Caltowie. Addresses on the subjects, "Feeding Dairy Cows" and "Poultry as a Farm Sideline," were delivered by Messrs. H. B. Barlow and C. F. Anderson. Mr. Dawkins presented trophies to the successful competitors in the Northern Crop Competition:—First, W. F. Wurst (87 points), barometer; second, C. Kleinig (86 points), £1; third, V. Walter (85 points), 10s. A

Delegates at Conference of Mid-Northern Branches held at Wirrabara on March 11th, 1931.

special trophy—entree dish, presented by the manager (Mr. Riley) of the National Insurance Company to members of Caltowie Branch—was won by Messrs. Neindorf Bros. The following resolutions were carried:—"That the Government be asked to extend the time of rail concession on super to June 1st." "That an endeavor be made to have better supervision of the quality and standard of cornsacks offered for sale by firms and issued to farmers."

There was an excellent representation of delegates from Women's Branches in the Conference district. Mrs. E. L. Orchard (Belalie) presided, and interesting papers were read. These were as follows:—"Poultry on the Farm" (Mrs. R. Noble, Nelshaby), "Art Needlework" (Miss R. Haines, Nelshaby), "Wet Frying" (Miss W. Stott, Eurelia), "How to Run a Kitchen" (Mrs. G. Smallacombe, Gladstone), "Homemade Bread and Yeast Cakes" (Mrs. F. Cumming, Belalie). Addresses were given by Messrs. Barlow and Anderson.

A paper and demonstration on the subject "The Uses of Hessian in the Home" was given by Miss E. Campbell, Dip. Dom. Econ. (Education Department).

"LUCERNE-GROWING IN SOUTH AUSTRALIA."

[By W. J. SPAFFORD, Deputy Director of Agriculture.]

INTRODUCTION.

The great bulk of the farmed part of South Australia is situated in climatic conditions usually described as being semi-arid, the remainder having a mild temperate climate, and although no difficulty is experienced in growing a considerable assortment of agricultural crops where sufficient rain is received, this does not apply to much of the State. The cereals, Wheat, Barley, and Oats, can be profitably grown in all districts possessing natural conditions good enough to support farmers, but to date we have discovered few other plants that can be economically produced in much of our country, except where sufficient water exists to enable crops to be grown under irrigation. A notable exception to this is one of the most

LUCERNE CROP.—Showing luxuriance of growth and heavy yield of forage produced in suitable conditions. Illustration of crop grown with irrigation on reclaimed swamp land of the River Murray.

important agricultural crops known to man, namely, Lucerne, which flourishes in semi-arid climates, and although requiring a good deal of water to reach its maximum production, nevertheless grows well wherever the cereals can be profitably produced in these climatic conditions.

Besides being one of the hardiest of the known agricultural crops for hot, dry conditions, Lucerne is one of the most palatable and nutritious foods for livestock, and all of the farm animals and birds maintain themselves and thrive on it. The crop has been cultivated for centuries in the semi-arid portions of Asia, as well as in parts of Europe, and in all places it produces an abundance of fodder of the highest quality, improves poor soils, and eradicates weeds.

It can be successfully grown in all types of soil, from loose open sands to heavy clay loams, and thrives in the limey soils which are so prevalent with us, and judged by the experience of the World with the crop, Lucerne will eventually play an increasingly important part in our agriculture, enabling farmers to practise the essential combination of cereals and live-stock.

HISTORY.

Lucerne is one of the very old agricultural plants, having been domesticated for thousands of years, and in man's rise in civilisation it has played an important part, and has been established by man in almost all parts of the earth. It spread from central Asia into Greece and Italy, then throughout the Mediterranean region and into northern Europe. The Spaniards took it to South America, from where it spread into North America, and the crop has done so well in the Americas, and so much publicity has been given to it by the United States that there are at present very few places in the World where it is not known.

In Europe the plant was called Lucerne, under which name it is still known in Australia, but the Americans use the Spanish name of Alfalfa, which was derived from the Arabic name meaning "the best kind of fodder."

Lucerne was introduced into Australia shortly after the first settlement by white man, and as early as 1806 the crop was referred to in a report by Governor King, wherein he said:—"Lucerne yields as many as three cuttings a year, but as it will not admit of being fed off few cultivate it." At first the progress made by the crop was rather slow, but there has been a progressive advancement in the area seeded with Lucerne, and in recent years this has been really rapid, and it appears inevitable, as the value of this wonderful fodder plant as an unirrigated crop for our ordinary wheat lands is realised, that it will become increasingly popular in this country.

DESCRIPTION OF THE LUCERNE PLANT.

Lucerne (*Medicago sativa*) is a perennial leguminous plant, being either more or less covered with soft hairs or almost smooth, which grows from 1ft. to 3ft. in height, producing fairly upright stems with many branches and much foliage. The stems all originate from a crown at the summit of the tap-root, which is situated above or at the surface of the ground. The leaves, which are arranged alternately on the stems, consist of three leaflets, are in all kinds wedge-shaped, but vary considerably, in some being relatively long and narrow, whilst in other varieties they are short and rounded. All leaflets are toothed at the summit. The flowers, which in different varieties may be any shade of violet from very pale to a deep reddish-purple, are typically pea-like in shape, though much smaller, and are arranged in loose clusters at the summit of each branch. There are two to six kidney-shaped seeds of a yellowish-green color in each pod, and they are about one-eighth of an inch in length: the pods being spirally twisted in two to four loose coils, open through the centre.

Swedish Clover (*Medicago falcata*), sometimes known as Yellow Lucerne, is a perennial plant with some resemblances to Lucerne, but is a shorter-growing plant with underground stems, bright yellow flowers, and sickle-shaped pods.

Another plant belonging to the genus *Medicago*, of interest is the so-called Sand Lucerne (*Medicago media*). This plant is considered to be a hybrid between *Medicago sativa* and *Medicago falcata*, and in habit of

AUSTRALIAN LUCERNE.—Typical plant of Australian Lucerne, showing erect growth, strong stems, freedom from excessive branching, and vigorous root system.

growth is more or less midway between the two, and produces flowers which may be snow-white, bright yellow, or any shade between these and deep purple. The crowns from which the stems spring are all located well below the surface of the ground, and many of the plants produce true root-stocks, and so do not suffer from extremes of cold, and are proper perennials. Considering that seedlings do not throw true to any type, it appears incorrect to call it a distinct species. Some of the varieties of Lucerne grown in cold climates, such as Grimm, Ontario Variegated, Cossack, Baltic, etc., appear to be selections from one or other of these hybrid Lucernes.

AUSTRALIAN LUCERNE.—Showing flower-heads opening and in full bloom, and seed-heads with some of the pods just coloring.

VARIETIES OF LUCERNE.

Although Lucerne is grown so extensively in the World, it is one of the few cultivated plants which have not been separated into a very great number of varieties with distinct names. The tendency has been rather towards specialising in a certain type of Lucerne for large tracts of country where natural conditions are somewhat alike, and then giving this type the name of the locality. For instance, the principal types are known by the name of the country of origin, as for instance:—American Type, Peruvian Type, Arabian Type, Turkestan Type, German Type, Australian Type, and so on, and these regional types are again subdivided into different types, such as the American Type being split up into Kansas-grown Alfalfa, Oklahoma-grown, Texas-grown, Nebraska-grown, &c.

LUCERNE LEAVES.—A, B, C, E, F, & G, showing variations in shape of the leaflets found in a crop of Australian Lucerne, typical in other respects. D & H show leaves of Variegated Lucerne.

In countries sufficiently extensive to include temperate and tropical climatic conditions, Lucernes are classified into types suitable for different climates, the principal classes being what are known as the "*hardy*" group, including those kinds able to withstand cold winters without suffering winter injury, and the "*non-hardy*" group, which consists of the varieties suited to the hot, dry conditions of semi-arid country, and to sub-tropical regions.

In all portions of Australia where Lucerne is extensively grown the winter climate is really mild, and as a consequence we only grow the so-called "*non-hardy*" type of Lucerne. As a matter of fact, although we place different locality names on the seed produced in the country, practically all of the Lucerne stands established in recent years consist of what has become known as the Hunter River Type of Lucerne. There are, however, several types of Lucerne advertised in the country from time to time, and so brief statements on some of them are given.

LUCERNE VARIETIES SUITED TO DISTRICTS WITH MILD WINTERS.

All varieties of Lucerne found to be suitable for semi-arid and sub-tropical conditions of climate are essentially pure *Medicago sativa*, and are not derived from strains of hybrid origin, as are many other varieties grown in colder climates. In countries where extremely cold winters are experienced they are looked upon as being "*non-hardy*," because they suffer very badly or are killed during the winter; but where mild winters are the rule they do well, starting to make growth much sooner in the spring, recover after cutting much quicker, and continue growing longer into the autumn than do the so-called "*hardy*" types of Lucerne.

They are all characterised by carrying flowers of a violet color, although in some varieties they are of a darker shade than in others. The crowns from which the stems develop are situated above or at the surface, and the stems are more or less upright in habit.

PERUVIAN LUCERNE.

The Peruvian type of Lucerne consists of two strains, one of which is almost smooth, whilst the other has so many hairs on all parts of the plants that the crop has a greyish appearance. Other than the difference in hairiness the two behave in a similar manner, and are usually grouped together, although some claim that the hairy strain is much the better of the two. Peruvian Lucerne produces very erect, upright stems which are comparatively coarse, and possess rather few branches. It is generally conceded that this is one of the best of the Lucernes because of this erect habit of growth and its power of commencing growing earlier than other kinds, continuing growing after other varieties have become dormant, recovering rapidly after cutting, and making strong growth during periods of short cool days.

ARABIAN LUCERNE.

With Arabian Lucerne is included Algerian Lucerne, the seed of which is given prominence at times. This type is fairly hairy, but less so than Hairy Peruvian. It is a very erect type, and is characterised by having soft hollow stems, and leaves of a lighter color than most other kinds. There is no other variety which starts growing so early in the spring, continues

so late in the autumn, or recovers so quickly after cutting, but these obvious advantages are more or less counteracted, because this variety only produces a light seed crop, and it is a short-lived kind. In many cases stands of Arabian Lucerne only last four years before becoming too thin to be profitable.

TURKESTAN LUCERNE.

Turkestan type of Lucerne is probably one of the best to withstand the great heat and great cold experienced in some parts of the semi-arid regions of the World. It is not such an erect grower as most other of the "non-hardy" kinds and has rather wiry slender stems, and a low-spreading, branched habit of growth. In good Lucerne-growing conditions it is not nearly so productive as some other kinds, and any popularity it has attained is wholly due to its extreme hardiness in cold, dry localities. This variety has rather narrow leaflets, and the plants are fairly hairy.

LUCERNE CROP.—Showing the stand of typical Australian Lucerne with erect habit of growth, strong stems, and freedom from excessive branching.

GERMAN LUCERNE.

The German type of Lucerne is very similar to the Turkestan in general behaviour, but it is a little better cropper. It is a more succulent plant, with broader leaves, and usually carries less hairs.

COMMON AMERICAN LUCERNE.

The Lucerne known as Common American includes several of the erect, rapid-growing types, but the kinds approaching the Peruvian and Arabian most certainly predominate, and so on the average it is a good deal superior to the Turkestan and German types.

PROVENCE LUCERNE.

Provence Lucerne seed is usually on sale in Australia at a lower price than locally grown seed. This type is very similar to Turkestan and German Lucernes, being a rather low-spreading, much-branched kind with

fairly fine-textured stems. It starts to grow early in the season, and continues late into the autumn. It is a fairly good variety for pasturing purposes, but is not nearly so productive as the more erect types when grown in good conditions or when irrigated, particularly if the crop is cut and carted off the land, or made into hay.

AUSTRALIAN LUCERNE.

The term Australian Lucerne is quite justified for most of the crops grown in this country, because there is very little variation in the behaviour of the types usually grown, at all events in the better lucerne-growing districts, and where irrigation is practised. There are noticeable differences between stands of Australian Lucerne in the shade of violet coloration of the flowers, in the shape of the leaflets, in the length of life of the plants, and in the amount of hairiness present, but most crops conform to what are expected from the so-called Hunter River type, viz., very erect growth of relatively coarse stems without a high proportion of branches, early start in the spring, rapid recovery after cutting, continuance of growth well into the autumn, rather dark violet color of flowers, and ready response to irrigation water applied in the summer.

Australian Lucerne appears to have been derived from Smooth Peruvian and Arabian Lucernes, and perhaps Common American also forms part of it, but whatever its derivation, the type evolved certainly suits the conditions in which it is usually grown, and at present it appears that the only type, not well known in the country, likely to do as well or better, would be Hairy Peruvian. When, however, we reach the stage of endeavoring to grow Lucerne where severely cold winters are experienced, we may get some help from the growing of the so-called "hardy" types which are not liable to winter injury.

LUCERNE VARIETIES ABLE TO WITHSTAND SEVERE WINTERS.

Although not of any importance in South Australia at present, and probably they will never be needed to any great extent in the country, there are some varieties of Lucerne capable of withstanding severe cold, even where the soil periodically freezes at the surface during the extremely cold winters usual in some localities. All of these kinds appear to have been derived from hybrids between *Medicago sativa* (Lucerne) and *Medicago falcata* (Swedish Clover), and are known as Variegated Lucernes, because of the great variety of colors found in the flowers. It is quite usual to find all shades between bright yellow and deep reddish purple, and not a bit uncommon to see snow-white flowers as well. These Variegated Lucernes do not produce nearly as much fodder as do the true Lucernes in good Lucerne-growing conditions, but their great advantage lies in the fact that they have rendered possible the production of heavy yields of high-class leguminous forage in places too cold to support true Lucerne. They have a spreading rather than erect habit of growth, and as the crowns are well below the surface, all the plants tend to produce a large number of stems to each plant. Some of the plants have true rootstocks, and as a consequence they tend to spread and make patches, but even those plants without the underground stems tend to make large clumps as they get older. The Variegated Lucernes are very long-lived, and carefully managed stands will outlast the ordinary kinds. The seed of all varieties of this kind of Lucerne is dearer than seed of ordinary Lucerne, and it is always likely to be so, because they are comparatively light seeders.

Several strains of Variegated Lucerne have been kept separate and distinct, but the two outstanding kinds are Canadian Variegated (also called Ontario Variegated) and Grimm Lucerne, both of which are fairly extensively grown in the northern portions of the United States of America and in Canada. Very similar to these two are Cossack, Baltic, Siberian, etc., but not one of these latter kinds has yielded so well as either of the former two when grown in the same conditions.

These Variegated Lucernes are of interest to us just now because two kinds of Lucerne which are being given some prominence—Tagerim and Western Port—appear to be selections from one or other of them.

CANADIAN VARIEGATED LUCERNE.

Canadian Variegated Lucerne originated in Ontario, and in all probability is a mixture of the two original importations of Variegated Lucerne, one from Baden in Germany and the other from Lorraine in France. The extreme hardiness of this variety appears to be due to the fact that some of the winters experienced in Ontario since it has been grown there have been so very severe that all the tender plants were killed and only the very hardiest remained, and it is from these particularly hardy plants that present-day stands were derived. It is probably the hardiest where cold is concerned, and the longest-lived of all Lucernes.

GRIMM LUCERNE.

Grimm Lucerne is very similar to Canadian Variegated, but is not quite so resistant to severe cold. It was introduced into the United States of America in 1857, and was first grown by Wendelin Grimm, from whom its name was derived.

REQUIREMENTS OF THE LUCERNE CROP.

Lucerne is certainly one of the hardiest of the cultivated crops, particularly for semi-arid climates, where much heat and dryness are common and where long dry spells are sometimes experienced, and in such conditions will produce more growth of high-class forage than will any other known perennial plant. It is not very fastidious as to the type of soil in which it grows, does not require much soil moisture near the surface, except for the germination of the seed, but on the other hand, flourishes in an abundance of sunshine and high summer temperatures. Despite the remarkable hardiness of the plant, there are certain special conditions in which the crop reaches its greatest luxuriance, such as well-drained deep soil fully supplied with lime, plenty of good water for irrigation or an unfailing underground supply only a few feet from the surface, absence of extreme frosts in winter, good seed, proper soil tillage before seeding, thorough cultivation during the life of the crop, and sufficient phosphatic fertiliser.

SOILS SUITABLE FOR LUCERNE.

Lucerne can be grown in all types of soil between light sands and heavy clays, but like most others of the cultivated crops, it does best in rich, deep, well-drained soils. What the crop does demand is good drainage and plenty of lime in the soil, and given these two essentials, it is not very particular as to the type of soil, and will usually grow very well. Although Lucerne uses a lot of water, it cannot tolerate an excess in the soil, and as a matter of fact soils liable to become waterlogged are quite unsuitable

for the crop until they are artificially drained. Its requirements for lime are enormous—probably greater than any other of the ordinary cultivated crops grown in similar conditions, and in some cases, Lucerne may take from the soil up to a dozen or more times as much lime, weight for weight, as some other crops. The plant appears to be unable to develop a proper root system in the absence of sufficient lime, and the leaves take on a yellowish color, and the stand soon thins out.

Although Lucerne grows well in heavy-textured soils, it prefers the more porous soils, because they are naturally well drained, and they enable the roots to penetrate deeply, which suits this deep-feeding plant. The roots of Lucerne plants have been found at great depths, but in normal soils the tap-root of year-old plants may be down 6ft., at the end of the next year 10ft. to 12ft., and ultimately extend 20ft. to 30ft. in depth.

Practically all soils in South Australia are suitable for the production of good crops of Lucerne, the only exceptions being the rather sour soils resting on a heavy clay, to be found in a portion of the Adelaide Hills district, and a small area in the South-East district, where buckshot-iron-stone soils overlie an impervious clay. Most other soils in the State are well supplied with lime, and have suitable texture for Lucerne-growing, but depending on the type of the soil and availability of water so will the preparation and after-treatment vary.

CLIMATIC CONDITIONS FOR LUCERNE.

As with most of those cultivated plants which have been domesticated for many centuries, types and varieties of Lucerne have been developed for nearly every set of natural conditions to be found in the World, and so it is almost literally correct to say that Lucerne can be successfully grown in all climates which will permit white man to live and multiply. The most favorable climates, however, are:—(1) What has become known as semi-arid, and (2) sub-tropical, and in these climates, when sufficient water is available and good management is practised, Lucerne gives its maximum returns. If very high yields of forage are being sought from Lucerne, it is essential that it be grown in districts where the winter weather is mild, for then growth is made by the plants during practically the whole year, whereas if much cold is experienced, the growing period is considerably lessened. In ideal lucerne-growing conditions it is possible to average seven hay cuts a year, but in very cold places, as, for instance, in the farthest-north lucerne-growing districts of Canada, only two cuts are expected.

The climate of all parts of South Australia is well suited to the growth of the ordinary type of Lucerne, and the limitations that exist as to the production of the crop, depend on water and soils and not on climate.

WATER REQUIREMENTS OF LUCERNE.

Lucerne being a summer-growing plant which produces a number of strong growths during each season if regularly cut or grazed, requires an enormous amount of water if it is to reach maximum development. The amount of water required by most cultivated plants has frequently been measured, and is usually expressed as the transpiration ratio, which means the amount of water required by the plants to produce 1lb. of dry matter. Dr. A. E. V. Richardson found in Victoria that in a year when wheat had a transpiration ratio of 231lbs., Lucerne had a ratio of 819lbs., and the figure for Oats was 332lbs., Peas 283lbs., and Rape 355lbs. He also found

that the transpiration ratio is double or even treble in mid-summer what it is for Lucerne grown in the winter. The great amount of water that can be utilised by Lucerne means that in semi-arid climates full returns are only secured from the crop if irrigation water is available, or if good underground water is not too far from the surface. On the other hand, although the plant can use a lot of water, it can make a wonderful bulk of growth on a comparatively small amount. If good underground water is to be found at least 4ft. from the surface, and not deeper than 8ft. to 12ft., there is no need for much moisture near the surface, except for the germination of the seed and the starting of the crop. Lucerne is a rather remarkable plant in that, although it can utilise a large amount of water, there are few of the cultivated plants able to withstand dry periods for such a long time, and then rapidly recover as soon as rain falls or irrigation water is applied. It is one of the most drought-resistant of the cultivated crops on the one hand, and on the other one of the best of crops to utilise heavy irrigation.

GOOD LUCERNE SEED IS A NECESSITY.

Lucerne being a crop that has to last for many years, it is essential that a good stand be secured in the year of seeding down the crop, and to make sure of this the best seed is a necessity. It is generally recognised by experienced Lucerne-growers that thorough soil preparation is necessary to ensure a good stand, but all the work expended in the production of a good seed-bed is wasted if poor seed is to be sown, because a good stand cannot be secured from such seed.

Only seed of a really bright appearance should be used, and preferably it should be a true yellow with an occasional tint of light green, because this is a sure indication that it was properly matured and harvested in favorable weather. Seed which is decidedly green was probably harvested before fully ripe, or else had suffered from a frost as it approached maturity. The brightness of the seed fades with age, and it usually becomes darker as well as dull-looking, whilst on the other hand immature seed is usually of a distinctly green color, even when it is not badly shrunk through being harvested too soon. It is generally recognised that the germination power of the seed becomes less and less as the brightness of the seed is lost, and a large percentage of brown seed indicates poor-germinating seed. Occasionally, otherwise good samples contain a fairly considerable proportion of "hard" seed, *i.e.*, seeds which will not germinate in the year of seeding, because their skins have become so hard that they prevent the absorption of enough moisture to lead to their germination. If there is any suspicion that "hard" seed is present, it should be refused, or else a germination test made, and if it is found that the proportion of seed which will not germinate is at all appreciable, a supply from another source should be sought.

A germination test is readily carried out by filling an ordinary saucer with sand, covering it with blotting-paper or a piece of cloth, moistening it with water, then counting a given number of seeds and placing them on the blotting-paper or cloth. If the saucer is now placed in a position where the variations of temperature are not very great, the good seed will germinate in from three to seven days, and if those that germinated are removed, it should be a simple matter to count the others and calculate the percentage germination.

Besides good germinating power the Lucerne seed should be quite free of seeds of Dodder and field weeds.

ESTABLISHING THE LUCERNE CROP.

Lucerne is such a hardy plant in almost every way that it is not difficult to establish good stands of it in any soil or in any suitable climate, provided ordinary care is shown, and so much is now known about all phases of the growing and management of the crop that stands of it should be secured with the same certainty as is the case with the cereals. Although it is usually quite an easy matter to get a good stand of Lucerne, it behaves as do practically all other cultivated crops, in that the better the preparation and care shown, the better the results secured. As a rule the Lucerne crop is seeded with the intention of producing a thick stand that will be maintained for a great number of years, and as the life of the crop depends upon obtaining a good stand in the year of establishing it, maximum results will only be attained if the very best soil preparation is given, high quality seed is used, the seeding is carried out at the correct time and in the best way, sufficient fertiliser is applied, and everything necessary is done in a proper manner. That this great care is fully justified for long-lived stands

PREPARING THE LAND FOR SEEDING WITH LUCERNE.—The Culti-packer is a suitable implement to pulverize and consolidate the surface soil, and so create an ideal seed-bed.

of Lucerne is easily realised when it is remembered that in good lucerne-growing conditions it is possible to maintain profitable stands for 30 years and upwards, and so any expenditure incurred in establishing the crop becomes but a small annual cost when split up over its life.

PREPARATION OF THE SOIL FOR SEEDING WITH LUCERNE.

The method to be adopted in preparing the land for seeding with Lucerne varies very considerably as to whether the crop is to be grown on sandy or heavy-textured soils, if to be irrigated or grown with the natural rainfall, if to be maintained as a long-time stand or as a short-period rotation crop, and whether the district is well supplied with rain or otherwise. Whatever the conditions, however, it is of the utmost importance that some soil preparation be given, and in most cases the more thorough the preparation the better the results, and in this connection it is unquestionably a fact

that more failures of Lucerne crops are due to poorly-prepared seed-beds than to all other causes. In a general way the ideal seed-bed in which to sow Lucerne consists of very fine soil almost free of clods, about 1 in. to 1½ in. in depth, resting on very compact underlayers; the compactness and the smoothness at the surface being the two essentials to ensure a good and regular germination of small seeds, such as those of Lucerne.

HEAVY-TEXTURED SOILS.

In preparing heavy-textured soils and all soils not liable to drift a good deal of work is required, because after these soils are stirred up many of them require a lot of handling to pack them together again, and to break down their excessive cloddiness.

If it is intended to irrigate the crop, the levelling of the land should be done some time before seeding, preferably some months before, so that the patches where the underlayers have been exposed will have time to become mellow. Some little time before seeding the land should be irrigated to germinate weeds, which will be killed with a cultivator. Another irrigation will now be given, and as soon as the soil is dry enough to carry implements, it should be cultivated and worked into good seeding condition, and the seed should be put in whilst the land carries enough moisture to lead to a full germination.

Where underground water is found at a reasonable depth under heavy-textured soils, as is the case in many of the flats in our North, between Burra and Mannanarie, the soil treatment necessary depends on the presence or absence of weeds. All land foul with weeds should be bare-fallowed for a whole season, by ploughing in July or August, and then cultivating or harrowing every time weeds are in evidence or a crust has formed on the surface after a rain. Under such treatment an ideal seed-bed free from weeds should result, and the soil will be in good heart, to give the Lucerne plants a really strong start. Where it is known that the soil is fairly free from bad weeds, the ploughing can be done in the winter, and a good seed-bed be prepared by the spring in time for seeding while the soil is still moist. To help reduce the surface to a fine tilth and to pack the underlayers, a culti-packer of some kind is very useful, although a corrugated roller, or for that matter, even a plain roller, will do the job, but not quite so expeditiously.

When preparing heavy soils where the crop is to be grown with the natural rainfall, and particularly in those districts where the average annual rainfall does not exceed 25 ins., bare-fallowing for a full season is essential if the very best returns are to be secured. Where the rainfall is greater, and weeds not bad, a short fallow of about three months gives plenty of time to prepare the seed-bed, especially if a cereal crop immediately precedes the Lucerne.

LIGHT-TEXTURED SOILS.

In the preparation of the light-textured soils liable to drift, such as sands and "fluffy" calcareous soils, the difficulty of securing a full stand is increased, because of the danger of the young seedlings being buried or injured by the drifting soil particles, and so it is advisable to adopt different practices than for the firmer lands.

When irrigation is to be availed of, much the same methods as for heavier land can be utilised, because the soil can be kept together with artificial watering, but the levelling will be done immediately prior to the watering given to germinate the weeds, so as to reduce the chances of drifting.

Where the crop is to be grown by natural rainfall or on underground water, best results are secured by seeding these light lands to a cereal the season before the Lucerne is to be sown. The stubble is allowed to remain, or at all events is not over-grazed by livestock, and if the soil is of a very loose nature a mixture of seed and superphosphate is drilled in with a disc-drill in the following autumn without any previous cultivation. A trip with the culti-packer or roller over the land before the seed-drill is used, helps to consolidate the land and leads to better results. If the land is not very loose and drifty after the cereal crop, and many weeds appear after the first autumn rain, a light disc-harrowing does much good, but it must be remembered that it is quite essential to leave enough stubble on the surface of the land to protect the young Lucerne plants from drift.

When land that is known to be infested with Lucerne Flea is to be seeded in the autumn with Lucerne, it should be properly bare-fallowed to rid it of the pest, and to do this it is essential that no weeds of any kind be permitted to grow. Fallowed land is rarely affected badly by the Lucerne Flea, because infestation can only come from the edges of the plot, where the insects hatch out, and it takes some time for them to travel any distance.

METHOD OF SEEDING LUCERNE.

Lucerne is usually seeded by drilling in the seed or broadcasting it on the surface and covering it with an implement, but it is found for almost all conditions that drilling is much the better of the two methods. The seed being so small it is absolutely essential that it be seeded to only a shallow depth, and the drill does this with more uniformity than can be achieved by any other system. Besides planting the seed at a uniformly shallow depth, which should not exceed 1 in. except in very exceptional circumstances, the seed can all be placed by the drill on the firm soil immediately below the top loose tilth, it is evenly distributed, and is covered for a certainty, all of which help to promote a fuller and more regular germination and so a better stand. Where other agricultural crops with small seeds as well as Lucerne are grown in quantity, a grass-seed attachment for the ordinary seed-drill is warranted, and helps in the even distribution of Lucerne seed through the drill, but sufficient regularity of seeding is secured if the seed is sown in admixture with Superphosphate, through the manure-box of the ordinary seed-drill. If the soil was properly prepared before drilling the seed there is no need for further treatment, but if it is still loose and open it could be culti-packed or rolled with advantage, although it is usually much better to do all the packing of the land before seeding rather than afterwards.

If fairly large areas are to be seeded by broadcasting, a small machine known as a "Cahoon" Broadcaster, which is carried by straps over the shoulders and rests against the chest of a man, is quite suitable for the purpose and leads to a fairly regular distribution of the seed. Broadcasted seed should be immediately covered with a light harrow of some kind, and advantage would usually follow a culti-packing or rolling and another light harrowing.

In low-rainfall districts where the Lucerne plants get no moisture other than the rain which falls, the crop is sometimes grown in rows sufficiently widely spaced to be able to cultivate the land between the rows. With this treatment much greater returns are secured than if the whole land is covered and the plants left to themselves. It appears at present that this method of growing the crop may be useful to increase the yields of seed in our seed-growing districts of low rainfall and high temperatures. It can be practised with advantage for the production of a small amount of summer greenfeed, on wheat-growing farms in low-rainfall districts. The seeding would be done by running the mixture of Superphosphate and seed through every third hoe of the ordinary seed-drill, and the cultivating could be done with a single-horse hoe if the area was small, and for larger areas with a multiple-row cultivator or any ordinary farm cultivator with lucerne-cultivating points.

TIME OF SEEDING LUCERNE.

Lucerne can be seeded either in the autumn or in the spring, and in those places where winter or early-spring frosts are extremely severe it is necessary to sow the seed in the spring, otherwise the young seedlings might be killed by the frosts, but fortunately this does not apply to the lucerne-growing districts of South Australia, and consequently the crop

CAHOON SEED BROADCASTER.—Suitable for broadcasting small agricultural seeds such as Lucerne, where the areas to be sown are too large to be done by hand.

can be started, in practically all places, in the autumn. Where this can be done it usually proves advantageous, because autumn sowing generally means, for all districts where irrigation is not practised, a more regular stand of lucerne, less weeds, much more forage the first year of the crop, and less damage during the first summer should it prove an extremely dry and hot season. For areas to be irrigated the seed can be sown whenever convenient to the grower, but here also the advantages lie with autumn-sowing. In the heavier-rainfall districts of the State the crop can be established conveniently in the spring, and the land is then prepared by ploughing it in the autumn or early winter, breaking it down in the early spring, and seeding when the soil has warmed up in October.

In most places where Lucerne is grown the seeding should be done in April if a good germinating rain falls, and if this is not possible it should be carried out by the middle of May. In some few localities, where the rainfall is light and the soils of a more or less sandy nature, the seeding can be done throughout the winter, even during July and August.

QUANTITY OF LUCERNE SEED TO USE.

No general recommendation can be made as to the quantity of Lucerne seed required, because it will vary so much with the location, and the management intended for each stand. For long-time stands, it is desired

to keep a thick, dense crop for as long a time as is possible, and as all Lucerne plants are not equally long-lived, some only lasting one year, some two years, some ten years, some twenty years, and so on, it is essential that plenty of plants be provided at the beginning, so that it takes a considerable time before the stand becomes unprofitably thin. On the other hand, if the stand is only required for a short period in a rotation, or is to be grown in low-rainfall country where crowded plants would rob one another of moisture, it would be quite wrong to use much seed when establishing the crop.

In South Australia: (*a*) where full irrigation is practised about 20lbs. of seed per acre should be used; (*b*) where irrigation water is used but in limited quantity, and where the crop is grown on good underground water, as in the country between Burra and Mannanarie, about 12lbs. to 15lbs. per acre is sufficient; (*c*) on the sandy land overlying underground water at 6ft. to 12ft., as at Narrung and around Lake Albert generally, 9lbs. to 12lbs. per acre is enough; (*d*) on the heavy-textured and calcareous wheat lands of the State 6lbs. to 8lbs. per acre will give good stands; whilst (*e*) on the sandy wheat-growing soils of the Mallee, 4lbs. to 6lbs. per acre will provide much forage for a number of years.

The quantities of seed mentioned for the different sets of conditions are dependent upon reasonably good soil condition being produced before seeding, and if for any reason sufficient preparation has not been given, at all events on the heavy-textured soils, more seed will be necessary, but it must be remembered that increasing the amount of seed does not counteract insufficient soil preparation. Again, if anything but the very best seed is being used the amounts must be increased.

Broadcasting the seed, and the inevitable irregular covering of it with harrows or other implement, means that it is necessary to use more seed than with drilling, if equal stands are to be secured, and in this connection the figures given above must be taken to refer to drilling.

“NURSE” CROPS FOR LUCERNE.

Most people who still advocate the use of a “nurse” crop when establishing Lucerne, do so on the grounds that the young plants require protection from frost, but because frost-damage is of such very rare occurrence in this country, there are only a few occasions when benefit of any kind is obtained from the practice. As a matter of fact, it is common experience with lucerne-growers, that “nurse” crops, no matter how thin they might be, retard the young Lucerne plants, and if the “nurse” crop makes strong, thick growth, and shades the young Lucerne plants for any length of time, many of the latter die, and in some cases whole stands have been killed right out. In nearly all cases it is preferable to prepare the land well, and sow the Lucerne seed by itself, and it will be found that the young plants are quite capable of withstanding the coolness of our winters and the heat of the summers, better than if other plants are present to protect them.

If sandy land, liable to drift, is to be seeded to Lucerne, without having a cereal crop preceding it, a light “nurse” crop will probably save some of the young plants from being cut off by the drift. In these cases about

15lbs. of Barley or 20lbs. of Wheat are enough to give ample protection to the young Lucerne plants, and it is essential that the crop be cut or grazed off not later than the middle of November.

In heavy soils which crust over very readily, the young Lucerne plants sometimes have difficulty in pushing their way above-ground, and in these conditions it is often of advantage to sow a cereal with the Lucerne. In such cases the cereal seedlings emerge without trouble and open up the way for the young Lucerne plants. For the purpose, 15lbs. to 20lbs. of any one of Wheat, Oats, or Barley is sufficient, and the cereal must be removed by cutting or grazing before it matures.

INOCULATION OF THE SOIL FOR LUCERNE.

In all countries where Lucerne is grown on soils deficient in lime, it has been found necessary to introduce to the soils the bacteria which live on the roots of Lucerne and collect nitrogen from the air, and until this is done the Lucerne does not thrive. The act of introducing the bacteria has become known as *Inoculation*. Fortunately it has not been found necessary, so far, to practise inoculation anywhere in South Australia, because it adds to the expense and trouble of establishing the crop, and in all places in the State where tried it has been impossible to see a benefit for the operation. There appears to be no way of knowing whether land needs inoculation or not, except that on all soils very deficient in lime it seems to be required, if Lucerne is to grow at all well.

If we ever find it necessary to inoculate the soil for Lucerne, and we may have to do it in the Adelaide Hills and parts of the South-East, the job can be done by distributing soil from a field where Lucerne has grown well. It is usual to apply 300lbs. or 400lbs. of soil per acre, and it is collected by removing the top inch of soil from a Lucerne field, and then taking the next 3ins. or 4ins. of soil. The soil can be distributed by broadcasting or drilling immediately before seeding the land to Lucerne.

MANURING WHEN ESTABLISHING LUCERNE.

Farmyard manure is a very suitable fertiliser for Lucerne, but should be applied to the crop after it has been established rather than beforehand, except when it is really well-rotted and is ploughed into the land some months before the Lucerne is to be seeded. Unless these precautions are taken many weeds will germinate with the Lucerne, and thin-out the stand. When establishing a crop of Lucerne there is no better fertiliser to apply than Superphosphate, and in practically all cases there is no need to use any other manure. In good lucerne-growing conditions, 2cwts. Superphosphate (45 per cent.) per acre can be drilled in with the seed, and a reduced quantity for other conditions right down to about $\frac{3}{4}$ cwt. in sandy soils where the crop is only to last four or five years.

LIME FOR LUCERNE.

Lucerne takes an enormous quantity of Lime from the soil, so much so that, probably weight for weight, it removes more than does any other cultivated crop which grows well in similar conditions. This means that if an attempt is to be made to grow Lucerne in a soil deficient in lime the shortage must be made good before the crop will be a success. Although

lime, in the form of air-slaked lime or ground limestone, can be advantageously applied to growing Lucerne, it is usual to make up the shortage before seeding the land. This is generally done by broadcasting about 2 tons of lime per acre after the land has been ploughed and cultivated, and some little time before seeding, and then harrowing it into the seed-bed.

AFTER-SEEDING TREATMENT OF LUCERNE.

Autumn-sown Lucerne that is grown for cutting needs practically no after-seeding treatment, at all events not until the spring, because any weeds which appear should be left during the winter, but they should be cut with a mower before they produce seeds, and be carted from the plot. From then onwards the plot will be cut in the ordinary way.

Spring-sown Lucerne that is grown for cutting needs some care bestowed upon it during its first year, for it must be cut often enough to prevent the weeds from choking it out, and at the same time it must not be cut so often that the roots are prevented from developing because of the want of leaf growth. In hot, dry years a spring-sown Lucerne stand in which many weeds are growing can be spoilt by a too-close cutting, thus exposing the young plants too suddenly to the fierce sunlight, after having been protected and shaded for so long by the weed growth.

Very little can be done one way or the other to a new stand of Lucerne grown for grazing purposes. During its first year it should be grazed rapidly each time that stock are put on it, and then be spelled until good strong growth has again been made, and on no account must stock be allowed to remain until they begin to pull up the plants, and on heavy-textured land stock should be kept off the crop when the land is wet.

New stands of Lucerne should not be cultivated in any way, and in most cases harrowing is all that will be required before they start making spring growth in their second year.

MANAGEMENT OF THE LUCERNE CROP.

Successful Lucerne growing consists chiefly in maintaining a profitably-thick stand for a long period of years, and in producing heavy crops of forage every year of the life of the stand. These two requirements are only met if a definite system of management is followed for each particular stand, but there are certain practices which local experience has shown to be applicable to most lucerne-growing districts, and the variations from the general rules are not very great except in a few isolated instances. Once a good stand has been established in reasonably suitable lucerne-growing conditions, attention must be given to its cultivation, the addition of manures, and to the cutting or grazing of the crop, if maximum returns are to be obtained, and some knowledge is required as to when and how to thicken up a stand if it be rather too thin at the start.

CULTIVATION OF THE LUCERNE CROP.

In all of the heavy-textured soils in which Lucerne is grown it is found that it pays to cultivate the Lucerne crop, just as it does other perennial crops and most strong-growing plants. This job should be done very thoroughly with an implement which will stir up these heavy soils without tearing the crowns of the plants too much. A few years ago it was con-

sidered good practice to use a disc cultivator with the full intention of splitting the crowns as well as stirring the land, but it is generally recognised nowadays that although splitting the crowns does not do a great deal of damage, it is better to leave them unbroken. For the purpose the rigid-tine cultivator with very narrow shares does the work very well, and will penetrate the soil no matter how heavy the texture, if the operation is carried out in July or August, just before the crop commences to make its first spring growth. The spring-tine cultivator fitted with special lucerne-cultivating points does the job fairly well, particularly when the soils are in ideal condition so far as moisture is concerned. Cultivation should not be given during the first year of the life of the stand, but the soil can be lightly stirred before the next spring. Harrowing after grazing or cutting always does some good, particularly so after the tramping of grazing livestock.

There is not the same need to cultivate Lucerne which is grown on light-textured soils, but very thorough harrowing of the surface at least once a year does much to keep the stand in good condition.

Cultivation helps the Lucerne crop, because—

1. It loosens the soil, so admitting air and water more readily, and reduces the losses of water by direct evaporation from the soil. This loosening is particularly useful where the crop has been grazed, because livestock tend to overpack the surface of the soil.

CULTIVATING LUCERNE.—Points suitable for fixing to implements for cultivating Lucerne without injuring the plants. A & C for spring-tine cultivators. B for rigid-tine cultivators.

2. The roots of Lucerne must breathe, and the useful soil bacteria living on the roots must have access to the nitrogen of the air, so that anything tending to increase the supply of fresh air to the soil is of the utmost importance.

3. The organic matter, in the form of leaves and animal droppings, is more or less evenly spread and incorporated with the soil, instead of being left in heaps on the surface.

4. The eggs and larvae of insects which affect the Lucerne plants are destroyed in large numbers by breaking them up, and by exposing them to weather and birds.

MANURING THE LUCERNE CROP.

All forms of farmyard manure stimulate the Lucerne crop and lead to greatly increased growth, and such manure can be applied at any time during the year, provided it is added soon after a cutting or grazing so

as not to foul the forage. If the crop is to be cut for green forage or for hay the manure should be well rotted, because if there is much straw or coarse matter in the manure, it not only interferes with cutting, but fouls the forage, becoming mixed with it whilst being collected with rakes or forks. Bird droppings constitute an extremely good form of farmyard manure for applying to Lucerne crops.

Whether farmyard manure is available or not benefits are to be secured from applications of superphosphate in practically all parts of the State where Lucerne is grown, and it is becoming generally recognised that it is good practice to drill superphosphate into the land immediately after cultivating it during the winter. In good lucerne-growing conditions, either where irrigation is practised or where the crops can draw on a good underground water supply a few feet from the surface, an annual dressing of 2cwts. Superphosphate (45 per cent.) is warranted. Where the conditions are not so good the amount of Superphosphate used can be reduced until it reaches as low as 56lbs. per acre per year for the short-period stands on the sandy wheat-growing lands of the Mallee districts.

CUTTING OR GRAZING THE LUCERNE CROP.

Lucerne is almost an ideal forage crop for cutting and carting to livestock, and, on the other hand, in our climate, it is also fairly suitable for being grazed off by the animals. There is no shadow of a doubt, however, that greatest stock-carrying returns are secured by cutting and carting to livestock, and that the stands last much longer if treated in this way, but in such a country as ours it is often an uneconomic proposition to follow this practice as against grazing the crop. It has become usual in this State, when Lucerne is grown under irrigation for dairy cows, to cut and cart the forage to the cows, but when unirrigated, and to be used by sheep or other farm animals, it is usually grazed off.

Grazing invariably shortens the life of the stand as against always cutting the crop, and at the same time produces less forage each season. When Lucerne is cut at the correct time, the buds at the crowns have just burst, and the shoots grow uninterruptedly and very rapidly to again attempt to produce a crop of seed, whereas when stock graze down the crop they eat the soft portions first, including the young shoots just leaving the crowns, and in all probability before they have consumed all the woody stems these young shoots have been nipped off two or three times. This preventing the new shoots from growing to any length, retards the growth of the plants very considerably, and whereas cut Lucerne will again be ready to cut in 20 to 25 days in the height of the season, grazed crops in the same conditions will probably be eight or 10 days later.

THE ADDITION OF OTHER CROPS TO LUCERNE.

Where Lucerne is grown for grazing purposes it is becoming an increasingly popular practice to sow one of the cereals in the crop each year, to add to the amount of forage grown in the winter and early spring. It is generally recognised that this extra cropping will shorten the life of the Lucerne stand, but it is claimed that the greatly increased crop is full compensation for this. In the heavy-textured lands of the northern districts, the fields are thoroughly cultivated during May, and about 1bush.

to 1½ bush. of Oats are drilled in to the acre with about 2 cwt. Superphosphate. The resulting crop is usually grazed very heavily with sheep well into the spring, by which time the Lucerne gets the upper hand. In some cases the Oats are allowed to come to head, when the mixture of Oats and Lucerne is cut for hay. In the lighter sandy soils, the land is thoroughly harrowed, and about 1 bush. of Barley, usually one of the two-rowed type, is drilled in to the acre with about 1 cwt. Superphosphate. The Barley is often allowed to mature sufficiently, so that a mixed hay is cut, which is used as the winter feed for cows or sheep, and the Lucerne crop is grazed from then onwards.

THICKENING-UP A THIN STAND OF LUCERNE.

Unless a regularly-dense stand of Lucerne plants is secured in the year of seeding, it is hopeless to expect the stand to last for the long period usually desired. If for any reason the germination of the seed is irregular, it is certainly good practice to re-seed the thin patches. These patches should be lightly cultivated up, preferably with harrows, seed broadcasted over the areas, and very lightly covered. The re-seeding must be carried out while the existing plants are young, because great difficulty will be experienced if attempt is made to thicken-up a stand of Lucerne by re-seeding, once the crop is properly established and the plants are getting old, no matter how thin the stand is.

RE-ESTABLISHING A LUCERNE STAND.

In nearly all places where a Lucerne stand which has persisted for a number of years becomes too thin to be profitably left, and it is desired to re-establish the crop, some trouble is met with, and it is usually found to be practically impossible to get a full stand immediately after ripping up the old plants. To ensure a full stand, the land carrying the thin crop of Lucerne should be ploughed so well that most of the old plants are killed, then be made to carry two non-leguminous crops in succession, before again endeavoring to get the Lucerne crop started. Where the Lucerne is being grown with the aid of irrigation water it is often possible to produce the two other crops in a little over one year, by seeding the land, after the original ploughing and cultivations, in the autumn or early winter with an early wheat for hay, cutting and carting it out of the way as soon as possible, immediately ploughing and working down, and seeding to Maize or some such crop, ploughing again in the early autumn, re-levelling and seeding to Lucerne as soon as properly prepared. If most of the old Lucerne plants were not killed by the original ploughing and working, it may pay to delay the seeding of the new Lucerne crop until the spring, when the land would be cultivated as frequently as is reasonable after the finish of the Maize crop and before seeding the Lucerne. Where irrigation is not being practised it will take two years to prepare for the new Lucerne crop: the first year Wheat should be grown, and this can be followed by Oats for hay in the heavy-textured land, and Barley for grain in sandy conditions.

LUCERNE-GROWING UNDER IRRIGATION.

In countries and districts where the climate is dry and hot and where ample good irrigation water is available, Lucerne reaches its maximum production, and in such climatic conditions the soil requirements consist only

of the need of good natural drainage and the presence of plenty of lime. Although Lucerne can profitably utilise a heavy supply of water, both of rain and by irrigation, it demands good drainage and very quickly suffers if an excess of water lies on or in the soil for even a few days, and as a consequence, when the crop is to be grown with the aid of artificial watering, the first essential is to ensure good drainage. Having selected the site for irrigating, the method of applying the water must be decided upon, because the amount and kind of soil preparation depends upon this factor.

METHOD OF IRRIGATING LUCERNE.

There are a great number of different methods of applying water to crops, but most of them are only suitable for very small areas and when special circumstances exist, and are too expensive or otherwise unsuitable for utilisation in the growing of large-field crops, such as Lucerne. For a perennial crop that has to be cut or grazed several times during the season, the only practicable methods of economically applying water are by:—

- a. Flooding the land,
- b. Using overhead sprinklers, or
- c. Running the water in furrows, and

one or other of these systems can be availed of for the growing of Lucerne. Which of these methods will be undertaken will depend on several factors, the principal of which are the soil type, the quantity of water available and the rate of supply, the contour of the land, the area to be watered, and the quality of the water.

Where plenty of water is available, both as to total quantity and the rate of supply, for all fairly level soils which are of sufficiently heavy texture so that they do not "wash" badly, and on the other hand do not set too hard on drying, the best method of irrigation is by flooding. On sandy lands and those that are liable to "wash," where water is limited, where the flow of water is relatively small, or where the slope of the land is more or less steep, overhead sprinkling or watering in furrows should be practised. When soils of that heavy sticky nature which set very hard when dry are to be used for growing Lucerne with irrigation, the crop should be sown in rows and the water run in furrows between the rows, otherwise before seeding with the crop the texture of the land should be improved with applications of lime, gypsum, or heavy dressings of farm-yard manure. If the area sown to Lucerne to be irrigated is fairly considerable in extent, overhead sprinkling will be found to be too expensive, and flooding will usually be adopted as the method of applying the water.

PREPARING THE LAND FOR IRRIGATED LUCERNE.

When land is irrigated by flooding it is carried out by filling level, dish-like plots, known as checks, or is distributed over the land by small ditches, or by movable pipes. In the former case much preparatory soil work is necessary, and the system is only economically possible on land that is comparatively level to begin with. The whole area to be irrigated is divided into checks, about half a chain wide and 5 to 7 chains long, by check-banks, the length of the plots being down a slight fall if it exists, but preferably the land should be nearly level in all directions, otherwise high

check-banks are required at the bottom end. The land is ploughed deeply, and so well cultivated that it is very free and loose, to facilitate the work of making check-banks and levelling the surface of the land. When in fit condition, the check-banks are made at right angles to the water channel if the land is level enough, and then the checks will all be rectangular in shape, but if the land is uneven or has a fairly considerable slope, the check-banks are made so as to follow the contour of the land. The check-banks can be made by striking-out and crowning-up with a single-furrow plough, and then filling in the furrows, and rounding them off with the leveller, when levelling the checks. An ordinary road-grader fitted with a longer blade does this levelling well, or a specially constructed soil-leveller can be made as follows:—Three planks 12ft. long and 12in. wide are fixed about 18in. apart, and parallel to one another, the front plank being sloped 45° forwards, the middle one sloped 45° towards the back, and the back one being vertical. The middle plank is 1½ins. in thickness and the others 2ins. thick. The planks are fixed together with struts and bolts, near the ends and in the middle, and carry a platform about 6ft. long and 2ft. wide at the middle at right angles across the top of the planks. This platform protrudes about 2ft. behind the back plank, and about 18ins. past the top of the first plank, and is used for the driver to walk backwards and forwards to control the levelling operations. All three planks are plated with iron, and the middle plank extends ½in. (no more) below the bottom level of front and back planks. By walking on platform towards the team, the driver makes the front plank cut into the soil, and when on back of platform the front is tilted up and the implement does not “bite” into the land. Two chains, with large links, and about 3ft. in length, are carried on the end bolts which keep the planks together, and are the points from which the team pulls the leveller. If the pulling point on one chain is taken back near the front plank the leveller is drawn obliquely, and the soil is delivered at one end to make check-banks, instead of regularly spreading the collected soil as happens when the implement is pulled square on.

The levelling must be done carefully so that no knobs are left more than 3in. higher than the general level of the ground. As it is of the utmost importance that the check-banks and the grade given to the land be disturbed as little as possible, all cultivations given after levelling must be lengthways with the checks, and never across the check-banks or round and round the checks. The growing of Lucerne by flooding in checks enables maximum returns to be secured, and the work of applying the water is considerably simplified, but the initial work of preparation is heavy and in some cases fairly expensive.

When flooding is to be practised without check-banks, the land must be fairly level, and the distribution is then done by means of small temporary ditches or by movable pipes. In both cases the land is very thoroughly cultivated, and any prominent knobs are removed and all noticeable hollows filled, with a leveller or buckscraper scoop. In the case of small-ditch irrigating, the water is let on to the land from the main channel at suitable places, and is distributed by small ditches, which are made with a small plough or by hand with a hoe or shovel, along the high places in the field. The water overflows from these ditches, and providing a good deal of care and attention is given by the irrigator, fairly even distribution of water can be accomplished. This system has the advantage that the initial cost of preparation is very low, but the application of water is fairly expensive,

because a man can only attend to a comparatively small area, and the distribution is rather uneven. The number of ditches used is enormous, but they are so small that they do not interfere with the ordinary field operations connected with Lucerne-growing, and after the initial watering it is only necessary to see that the ditches are kept open, and that the water has a free run.

Where the water for irrigation is obtained from wells on the property, or is reticulated by pipes instead of in open channels, a suitable method of distributing the water is by means of movable pipes. Depending upon the area to be watered, the size of the pipes varies, but they usually consist of galvanized-iron downpipe, 4ins. to 8ins. in diameter, in short lengths easily handled by a man, which push together, the joint being made by a short piece of canvas hose fixed to one end of each pipe. The distributing line of pipe is shortened or lengthened as required. According as the land is well graded or not, so will small ditches through the crop be necessary to help in the regular distribution of the water.

If Lucerne is to be irrigated in furrows, it is usually grown in parallel rows, and the spaces between the rows are opened up as small ditches to carry the water. If the land has a regular and gentle grade the rows can be made as straight lines, but if the land is irregular they should follow the contour lines. This is an excellent manner in which to grow Lucerne, where water is limited, and where soils are light and liable to wash. It is very easy to prevent over-irrigation, and if cultivators are put on the land soon after every irrigation, fairly saline water can be used, and the rise of salt from saline lands is delayed. Sometimes the Lucerne is seeded as a full crop, and after germination shallow furrows parallel to one another are made in the crop. The spacing of the rows depends on the soil type, being much closer in heavy-textured soils where the tendency to soak sideways is not great, and wide apart in light, open soils. These furrows are cleaned out each season, and so become permanent ditches to carry the water.

Where the land is steep, uneven, liable to wash because of being loose and open, and the areas not large, irrigating by overhead sprinklers is often availed of. The only soil preparation necessary is to fill hollows, and reduce prominent knobs. This method of watering is more economical of water than any other, and so is useful where the water supply is very limited, and is usually practised where the water is expensive.

SEEDING LUCERNE THAT IS TO BE IRRIGATED.

No matter what system of irrigating is to be practised, considerable expense is incurred in preparing the land and providing the water and the means of distribution, and so it is essential that a good thick stand of Lucerne be secured in the year of seeding. To ensure a really good germination of the seed the plot should be irrigated beforehand, and as soon as implements can be safely put on the land the seed-bed should be prepared, and the seeding be carried out while there is still sufficient moisture in the ground to lead to a full germination. If for any reason the moisture should dry out to the extent of making a full germination doubtful, the land should again be watered rather than risk a poor stand. It is a matter of common experience that much better results are secured by irrigating before seeding, and that trouble with the germination is to

be expected if the watering is left until after the seed has been put in. If the land is weedy, an irrigation should be given to germinate the weeds, and after they have been killed with cultivators, the pre-seeding watering should be given. About 20lbs. of seed should be drilled in to the acre in admixture with 2cwts. Superphosphate, being certain to run the drill rows in the direction of the flow of water, otherwise the rows of Lucerne plants will retard the run of the water instead of facilitating it. The seeding should be done in the autumn, when the first-year Lucerne will give nearly as high a return as older stands.

IRRIGATING THE LUCERNE CROP.

The system adopted for irrigating the Lucerne crop has something to do with the amount of water used and the time of application, but not nearly so much as does the quantity of water available, and the type of soil in which the crop is being grown. Although the crop is able to utilise an enormous amount of water in hot seasons and in fertile well-drained soils, the yields secured are not proportionate to the amount of water supplied, and the Law of Diminishing Returns applies to the yields of Lucerne received when increasing the supply of irrigation water. The amount of water available is of first importance when deciding the details of water application, for depending on this is whether maximum returns per acre will be sought or whether maximum returns for available water will be the aim. In his experiments, Samuel Fortier found that 30ins. of water applied to one acre of Lucerne gave a return of about 14,400lbs. of hay, whereas when the same quantity was applied to five acres, the return was about 64,100lbs. of hay. When plenty of water is at hand frequent and heavy applications can be given, but when water is scarce it would probably be better to make it cover as large an area as possible. Next in importance in regard to the application of the water is the texture of the soil, because both the quantity and time of irrigating will vary with the soil, and in this connection it is usual to find that frequent waterings are necessary for open, porous soils, whilst fewer but heavier applications suffice for heavy-textured soils with good water-holding powers.

It is claimed by some Lucerne-growers that in hot climates the roots of the plants should be encouraged to go downwards as quickly as possible, and that it can be done by watering the young stands for the first two years only when absolutely necessary. This does not appear to be essential in our conditions, for where the young stands have been liberally irrigated the returns are very considerably increased, and the plants appear to live just as long as if hardened whilst young.

To get the most out of well-established Lucerne crops, water should be applied as soon as the plants begin to show that they need it. The application of water after the plants have taken on the characteristic bluish color, which is always accompanied by toughness, starts the new growth from the crowns but does not freshen up the old toughened growth. If for any reason the watering has been withheld until the crop has suffered, it should be cut and then can be watered with more advantage. In those locations where the soils are rather porous, one watering each cut in the early part of the season is all that is required, but as the season advances and the temperature increases so must more waterings be given; still, in most lucerne-growing districts of the State one irrigation per cutting gives full returns. Where only one irrigation is given for each cut, it can be

applied either just before or immediately after the cutting, and equal results can be expected from a given quantity of water. If given before cutting the crop, the flow of water is retarded by the mass of growth, and so it is usually much better to irrigate immediately after cutting, when the job can be done more easily. Some heavy-textured soils set hard and crack badly if irrigated soon after the Lucerne is cut, and in such cases the watering should be done when there is sufficient growth to properly shade the surface of the soil. Where overhead sprinklers are being used, highest returns will be secured if a watering is given a few days before and again a few days after the crop is cut. When the irrigation is being done by flooding or in streams in furrows, the flow should be nice and steady, so that the water has time to saturate the surface soil and sink into the subsoil; the flow can be faster for light-textured soils than for heavy, close-grained ones. The pace of the water should be such, in average conditions, that it takes about eight hours to run from the main channel to the bottom of the checks or rows.

The quantity of water required for the production of maximum Lucerne crops varies with a great number of factors, but in our climate and in good loam soils with fairly high water-holding power, from 30ins. to 45ins. of added water per acre will be required. The smaller quantity will be used where the water is applied by sprinklers, and will be given in ten waterings, each of about 70,000 gallons per acre. One watering would be given to the first and last cuts, and two to each of the other four cuts. The larger quantity of water will be required where flooding is being practised, and in this case six or seven applications of from 6ins. to 8ins. per acre will be given. If the watering is to be done in furrows something between these two limits will be necessary. Extremely good crops of Lucerne can be grown with less water than the quantities mentioned, but there are few locations in this State, where no underground water exists comparatively close to the surface, where maximum crops will be secured with lesser quantities. Lighter crops will be secured if smaller amounts of water are supplied, yet it will in many cases be more economical to use less water per acre, and spread the available quantity over a greater area. Where the average annual rainfall is from 16ins. to 20ins., there should be available about another 20ins. of water for every acre of Lucerne to be irrigated; more water will mean heavier crops per acre, or greater areas to be sown.

It is essential to remember that soils not well drained are quite unsuitable for growing Lucerne with irrigation, as the yield is always reduced even if the water-logging only lasts for a comparatively short time. Further, in a hot climate like ours, the plants are readily scalded, and if on a hot day, water from flooding, takes a few hours to soak into the soil, the crop is often injured. Scalding of the plants, to the extent of burning the whole of the growth, often follows the slow sprinkling of the crop, particularly if the water is a little saline, if the watering is done on a hot day when the sun is shining fiercely. When sprinkling Lucerne in the day-time, the stream of water should be such that there is no danger of the plants becoming wet and dry several times during the operation; the pressure should be such that the crop will be watered quickly, and this precaution is the more necessary the greater the amount of total soluble salts in the water.

(To be continued.) In the next issue, the article will deal with Utilisation of the Lucerne, Production of Lucerne Seed, Diseases and Pests.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on March 25th, there being present:—Messrs. F. Coleman (chair), A. M. Dawkins, P. J. Baily, H. S. Taylor, A. J. Cooke, P. H. Jones, A. L. McEwin, R. H. Martin, Professor A. J. Perkins (Director of Agriculture), Dr. A. E. V. Richardson (Director of Waite Research Institute), Messrs. W. R. Birks (Principal Roseworthy College), and H. C. Pritchard (Secretary). Apologies were received from Messrs. G. Jeffrey, H. N. Wicks, and S. Shepherd.

Sale of Bran and Pollard.—At a Conference of Southern Branches, held in August, 1929, the following resolution was carried:—"That this Conference favors the introduction of legislation to fix a standard quality for bran and pollard." The matter was referred to the Chamber of Commerce, and was taken up by the Mill Owners' Association, whose representatives stated that whilst they believed it would be difficult to establish legitimate standards for bran and pollard, because these substances were normal residues in the manufacture of flour, they recognised the necessity of protecting users from unscrupulous adulteration. Copies of legislation existing in Western Australia and Queensland have been obtained and the standards set out are as follows:—

Bran (Western Australia).—The Second Schedule of the Act quotes the following:—"Bran shall consist of the outer skin or coating of the wheat grain or berry obtained in the usual commercial milling process from wheat. There shall not be more than 1 per cent. of foreign ingredients. It shall contain (subject to the undermentioned limits of variation) not more than 10.5 per cent. of moisture, nor more than 9 per cent. of fibre, nor more than 4 per cent. of ash, calculated on a moisture content equal to 10.5 per cent. Limits of variation: Moisture and fibre 1 per cent., ash $\frac{1}{2}$ per cent."

Pollard (Western Australia).—Pollard shall be a byproduct of milling wheat, other than flour and bran, in which there shall not be more than 1 per cent. of foreign ingredients. It shall contain (subject to the undermentioned limits of variation) not more than 10.5 per cent. of moisture, nor more than 5 per cent. of fibre, nor more than 2 per cent. ash, calculated on a moisture content equal to 10.5 per cent. Pollard shall be of such fineness as to permit of 50 per cent. passing through a silk-cloth or grit gauze sieve with 24 meshes to the lineal inch. Limits of variation: Moisture 1 per cent., ash $\frac{1}{2}$ per cent.

The Act provides that the Governor may by regulations prescribe substances which shall be deemed foreign ingredients, but the Western Australian Department of Agriculture states that there are no regulations so far as bran and pollard are concerned. There is a clause in the Act which provides that if any person sells for use as food for stock any article which contains any ingredient deleterious to stock, or to which has been added any ingredient worthless for feeding purposes and not disclosed in writing to the purchaser at the time of sale, he shall be guilty of an offence against the Act.

Bran (Queensland).—"Bran shall consist of the outer skin or coating of the wheat grain or berry, pure and without admixture of any kind, obtained in the usual commercial milling process from wheat from which there shall have been removed all impurities by cleaning and scouring. (It must not contain any whole or broken wheat grain, and only 1 per cent. by weight will be allowed of any substance of a non-deleterious character other than the byproducts of wheat. Bunt, not more than 0.1 per cent. by weight)."

Pollard (Queensland).—Pollard shall consist of the products of the wheat grain or berry (other than flour or bran) obtained in the usual commercial milling process from wheat from which there shall have been removed all impurities, and shall be of such fineness as to permit of 99 per cent. passing through a metal sieve perforated with round holes 1.5mm. in diameter. (Foreign ingredients allowed: Any substance of a

non-deleterious character other than the byproducts of the wheat, 0.5 per cent. by weight. Any wheat byproduct that will not pass through a metal sieve, as referred to above, 1 per cent. Bunt, not more than 0.1 per cent.)

No proportion or amount of the following will be allowed for bran or pollard:—Ergot, plants, parts of plants and seeds of dodder, thorn apple, castor oil plant, physic nut, poppy, kahaki weed, corn cockle, Bathurst burr, Noogoora burr, or any substance of whatever character in itself deleterious to the life or health of stock. Nor any substance of whatever character added for the purpose of fraudulently increasing the weight of the foods. Nor any stock food listed as being of low food value, unless the actual amount is declared on the invoice and label. As regards moisture, the allowance is 13 per cent. by weight, unless the actual amount is declared on the invoice and label.

It was decided to ask the Director of Chemistry for an expression of opinion as to whether the legislation outlined by the Queensland and Western Australian Departments of Agriculture could be used as a basis for introducing a standard for bran and pollard in South Australia.

Conference Resolutions.—The following resolutions were received:—*Mid-North Conference*: "That an endeavor be made to have better supervision of the quality and standard of cornsacks sold by firms and issued to farmers." *South-Eastern Conference*: (a) "That it be a recommendation from this Conference that potatoes and grain, other than wheat, be allowed to be marketed in washed super. bags." (b) "In future, evening sessions be cut out, and that Free Parliament be brought on earlier after luncheon."

Ridley Memorial Scholarship.—Mr. A. M. Dawkins was re-appointed as the Board's representative on Ridley Memorial Scholarship Committee.

Life Members.—Life membership of the Agricultural Bureau was conferred upon Messrs. W. E. Rogers (Naracoorte) and R. L. C. and P. S. Sinclair (Green Patch).

New Members.—The following names were added to the rolls of existing Branches:—Pinnaroo Women's—Mrs. H. Ide; Saddleworth—Olaf Coleman; Millicent Women's—Mrs. A. Redman; Kangarilla—L. G. K. Roberts; Cummins—R. D. Olsson, W. E. Bryant, C. Williams, A. Waters, W. G. Haines, A. Williams; Yadrnario—C. J. Silvertsen; Buchanan—R. Rohde; Boors Plains—L. Northey; Bundaleer Springs—L. Seigert, E. Seigert; Springton—H. A. Kluge, L. P. Hermann; Kalangadoo—J. Hunt. No. of Branches, 305; total No. of members, 8,458.

Herd Testing Associations.—The following resolution was received from the Balhannah Branch:—"That the Herd Testing Associations be continued." The Secretary was instructed to advise the Branch that this matter was being considered by the Government.

Rail Concession on Super.—The Mid-North Conference resolved "That the Government be asked to extend the time of rail concession on super until May 31st." It was decided to forward the resolution to the Railways Commissioner through the Minister of Agriculture, with the support of the Board.

† Dead.

DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & CO., LIMITED, reported on April 1st, 1931.

BUTTER.—The market throughout March continued fairly steady, only slight fluctuations occurring during some weeks. This was due to the London market keeping fairly steady, and although South Australia exported very little during the month, values were largely influenced by overseas rates in sympathy with the movements in the various States of the Commonwealth. Production is now rapidly declining, and must continue to do so until the break of the season and the growth of the pastures. Consumption kept up fairly well considering the lower purchasing power of the people, and at the close of the month prices were as follow:—Choicest creamery fresh butter, in bulk, 1s. 7½d. Prints and delivery, extra. Second and third grades, 1s. 5½d. (These prices are subject to the stabilisation levies.) Best separators, 1s. 4d. to 1s. 5d. Well-conditioned store and collectors', 1s. 1d. to 1s. 2d.

EGGS.—There were sharp rises in the values of eggs during the last week or two of March, due to the rapid decrease in production coupled with the fact that the Lenten demand was very much stronger. The quality of the eggs also shows an improvement owing to the cooler weather conditions, and ready clearances were effected of all lots. Ordinary country eggs, fresh hen, 11d. per dozen; duck, 1s. per dozen; selected, tested, and infertile, higher.

CHEESE.—Moderate demand continued for new cheese, although there was better call for semi-matured and matured lines. Local traders operated well, but Western Australian buyers of new cheese transferred their buying to Queensland brands to some extent, because of the lower quotations offering. New makes, large to loaf, 7½d. to 8½d. per lb.; semi-matured and matured, 11d. to 1s. per lb.

ALMONDS.—Heavy quantities of almonds were again marketed throughout the month, and alarm was felt in some directions over the projected removal of duty on kernels. This alarm, however, was somewhat premature, as later information revealed that the duty was only to be removed under certain conditions and on specific lines for manufacturing purposes. Brandis, 6d. to 6½d.; mixed softshells, 5d. to 5½d.; hardshells, 3d. to 3½d.; kernels, 1s. 3d. to 1s. 4d. per lb.

HONEY.—There was an improved demand for all grades of honey during the month, but more particularly for prime, clear extracted, new season's. Quite a lot of the honey was not up to the standard of choicest, this being due to the poorer flowering season in many districts. Prime, clear extracted, in liquid condition, 3½d. to 3½d. per lb.; best quality candied lots, 2½d. to 3½d. per lb.; second grade, 1½d. to 2d. per lb.

BEESWAX met with moderate demand, with ample stocks at all times offering. Rates nominally 1s. 3d. to 1s. 4d. per lb., according to sample.

BACON.—As usual with the nearer approach of winter conditions, the demand for bacon improved, and although regular heavy consignments were received from the various factories the stocks were cleared from day to day. There was a slight easing in rates for some cuts. The sale for hams showed a falling away at the beginning of the month, but with the nearer approach of Easter a better call was experienced from the ham shop and cafe proprietors. Best local sides, 9½d. to 10d.; best local factory-cured middles, 9d. to 9½d.; large, 8½d.; local rolls, 8d. to 8½d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 2d.; local hams, 1s. to 1s. 1d.; cooked, 1s. 3d.; "Sugar Cane" brand lard, in packets, 11d., in bulk, 10d. per lb.; local prints, 9d. per lb.

LIVE POULTRY.—Increasing supplies of live poultry were received for each auction sale as Easter drew nearer, and almost record quantities were catalogued. The demand, however, was maintained better than might have been expected, and although prices were lower than for several years past, this was anticipated because of the general lower trend of all commodities. Prime roosters, 3s. to 4s. 3d.; nice-conditioned cockerels, 2s. 3d. to 2s. 10d.; fair-conditioned cockerels, 1s. 8d. to 2s. 2d.; chickens, lower; heavyweight hens, 2s. 8d. to 3s. 7d.; medium hens, 2s. to 2s. 6d.; light hens, 1s. 6d. to 1s. 11d.; couple of pens of weedy sorts, lower. Geese, 2s. 9d. to 4s.; prime young Muscovy drakes, 3s. to 4s.; Muscovy ducks, 2s. to 2s. 9d.; ordinary ducks, 1s. 6d. to 1s. 11d.; ducklings, lower. Turkeys, good to prime condition, 7d. to 9d. per lb. live weight; turkeys, fair condition, 5½d. to 6½d. per lb. live weight; turkeys, fattening sorts, lower. Pigeons, 3½d. to 4½d. each.

POTATOES.—Local, 5s. to 5s. 6d. per cwt.

ONIONS.—Brown, 5s. 6d. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of March, 1931, also the average precipitation to the end of March, and the average annual rainfall.

| Station. | For Mar. 1931. | To end Mar. | Av'ge to end Mar. | Av'ge Annual Rain-fall. | Station. | For Mar. 1931. | To end Mar. | Av'ge to end Mar. | Av'ge Annual Rain-fall. |

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

REPORTS OF BUREAU MEETINGS. WOMEN'S BRANCHES.

BREADMAKING.

[A paper read by MRS. W. VARCOE (*Millicent*) at the Kalangadoo Conference.]

Bread stands at the head of all foods. It has been correctly termed "The Staff of Life." Wheat, from which bread is mostly made, contains more nearly than any other one article all the necessary food elements required to sustain the human system, and so forms nearly a perfect food. Home made bread, when properly prepared, is much to be preferred to baker's bread. It is also much cheaper and keeps fresh longer. Day-old baker's bread is as dry as week-old home made (that has not been overcooked). Every housewife ought to know how to make good bread. Three essentials to good breadmaking are—good yeast, good flour, proper attention and baking. Good flour is of a creamy white color, and when a pinch is held between finger and thumb, and well rubbed, it should remain separate in grain and not adhere together or become sticky, which it will do if at all damp. You cannot make good bread from damp flour. Australian flour is acknowledged to be the best type of flour the world produces. Wheat grown in the Northern districts is much superior to wheat grown in the lower South-East, as our climate is not suitable for growing wheat for flour. Owing to our cool summers, wheat ripens slowly, is browner, and the grain has a thicker skin. Flour made from it has a darker color and is moister, consequently bread made from it is not so white or light as that which is made from flour produced in the drier, warmer parts of Australia. *To Make Yeast.*—Take 1 tablespoonful hops, 1 tablespoonful salt, 1 tablespoonful sugar, and 2 pints of boiling water. Boil all together for 2 minutes. Grate 2 medium-sized potatoes in a basin. Mix in 1 tablespoonful of flour. Strain yeast, and, while boiling, pour it into the basin of flour and potatoes, stirring all the time. Stand aside until cold. Then half fill the bottles. Cork tightly and tie down corks. Stand in a warm place until it works, when it is fit to use. It will keep good for a fortnight at the least, and I have had it keep for more than a month. *To Make Bread.*—Take 6 heaped cupfuls of flour, or 2 cups of flour and 4 cups of whole wheatmeal, 1 level tablespoonful of salt, 2 cupfuls of yeast. Put the flour in a deep pan, make a well in the centre, stir in 1 pint of water (as hot as you can bear your hand in). Stir well together from the centre until a thick paste is formed. Then add the yeast, mix all together until a large loaf is formed, add a little more flour if you find dough is too soft. Leave in pan, cover with a cloth, wrap a blanket round and leave set out until morning, when it should be twice its original size. Prepare the tins by greasing them inside. Weigh the dough—about 2lbs. 2ozs. to make a 2lb. loaf. Knead and put in tins, set in a warm place near the stove. When it has again risen to twice its original size, bake in a moderately hot oven for one hour. Pastry made from yeast dough is very nice. Roll out a pound of dough (when fit to put in baking tins). Take 10ozs. dripping or lard, spread some over the dough. Fold over in three and roll out again. Repeat spreading the shortening, folding and rolling about six times. Then use for covering meat or fruit pies. It is delicious when eaten hot. *To Make Brounie.*—Take about 2lbs. of dough after it has risen. Spread it out on the board or mix in a pan. Mix into it 1 cup of currants, raisins, or any fruit liked, 1 small cup of sugar, a little more than half a cup of butter or dripping, and a little cut up lemon or orange peel. Knead all together well, adding a little more flour. Put in tins the same as bread. Stand aside to rise, and bake the same as bread in an oven not quite so hot as for bread. This is a good recipe for yeast buns—½lb. butter, 1 pint milk (hot). Dissolve butter in milk, ½lb. sugar, 4 eggs (well beaten), 1 large cup of yeast, currants, raisins, dates, and peel to taste. Sufficient flour to make a rather soft dough. Mix all ingredients together, let dough rise all night, make into buns in the morning, and bake in a quick oven. Brush over with sugar and milk about five minutes before taken out of oven. This mixture with a softer dough makes a rich German cake.

AUBURN (Average annual rainfall, 24.08in.).

February 27th.—Present: 12 members.

SAUCES AND PICKLES.—Mrs. Morecom gave the following recipes:—When making tomato sauce always select sound, ripe fruit, the overripe fruit is too full of juice, and the sauce will be too thin unless the quantity of vinegar is reduced. The following is a reliable recipe:—12lbs. tomatoes, 3 pints vinegar, 4ozs. shallots, 4ozs. garlic (or onions), 2ozs. white pepper, 8ozs. salt, ½oz. cloves, ½oz. ground ginger, ½oz. mace, ½oz. ground allspice. Cut tomatoes and onions in pieces, boil to pulp with vinegar and spices, then strain. Add 1lb. sugar and boil about 2 hours. *Pickled Figs.*—4qts. vinegar, ½lb. white sugar, ½lb. salt, ½oz. pepper corns, 2ozs. each allspice, cloves, and ginger. Soak ripe figs in the liquid for three days, then pour it off and boil. Add the boiling liquid to the figs and allow the pickle to stand one month before using. *Mustard Pickles (Cauliflower).*—6lbs. cauliflower, 2 cups sugar, 1 teaspoon mustard, 2 teaspoons turmeric, 1 teaspoon curry powder, 1 tablespoon salt, ½ cup flour, ½ oz. cloves, 2qts. vinegar, ½oz. whole allspice. Method: Cut up cauliflower over night and stand in salt water. Next day strain and boil until tender, in fresh water. Drain well and add to the other ingredients. Mix mustard, &c., to a smooth paste and add to boiling vinegar. Boil for 10 minutes, add cauliflower and boil all together until pickle has gone right through vegetable. (Secretary, Miss L. Dennison.)

EURELIA (Average annual rainfall, 13.06in.).

September 3rd.—Present: 16 members and one visitor.

Recipes for cold meats were read and discussed by members. The following recipes were submitted:—*How to Make Hot Dishes from Camp Pie Meat.*—No. 1—Put all into a saucepan with a pint of boiling water, then thicken with flour, and serve with mashed potatoes; it also makes splendid sausage rolls. No. 2—Slice pie in ¼in. slices; make a batter of two eggs, a little milk, a cupful of self-raising flour, and a pinch of salt; dip the slices of camp pie well into the batter, then fry in dripping or lard till nice and brown. This is a good dish to serve with chip potatoes. No. 3—One tin (large) of camp pie, one onion, three potatoes; put through the mincer with onion; cook potatoes, mash them with a little butter and milk, add the meat; mix well together; put in a pie dish, lightly greased; bake in a fairly hot oven one hour. *An Easy Way to use up Cold Mutton.* *Mutton and Potato Pie.*—Two pounds of cold mutton, 2lbs. of potatoes, two onions, salt, and pepper. Cut the meat into small, thin slices, partly boil again. Put on the bottom of pie dish a layer of potatoes, then a layer of meat, and a few slices of onion, and season with salt and pepper. Repeat until all the ingredients are used, the top layer being potato. Pour the gravy in which the meat was boiled (about ½ pint). Cover with a greased paper and bake about one hour. A quarter of an hour before serving, remove the paper to allow the potatoes to brown. *Quarter of an Hour Stew.*—Ingredients, 1lb. to 1½lbs. cooked meat, stock or water, pepper and salt, two large onions. Place the onions in the frying pan and cook till brown. Pour off the fat used for frying onions and add stock or water. Let these boil for a few minutes, add the meat, finely chopped, and let all simmer for about 10 to 15 minutes to taste. Add thickening of flour and water. Serve when quite hot. This stew is delicious and uses up any odd pieces of cooked meat unsuitable to put on the table. *Cold Meat with Macaroni.*—One pound of any cold meat (minced), one cup bread crumbs, two eggs, little milk, salt and pepper. Mix well together; boil ½lb. of macaroni for 20 minutes in salted water, then strain. Butter a bowl, line it with macaroni, then put the meat mixture in. Cover with the rest of the macaroni. Cover bowl with butter paper and steam one hour. Serve with parsley sauce. *Savoury Pie.*—One pound cold roast beef, four tomatoes, two onions, 2ozs. grated cheese, butter, salt and pepper, and bread crumbs. Chop meat finely, melt butter, and fry onion; add meat, salt and pepper, and sliced tomatoes; simmer gently for 15 minutes. Grease a pie dish and pour into it a layer of mixture and sprinkle with bread crumbs and cheese. Add tomatoes, then rest of meat, &c. Bake in moderate oven 20 minutes. *Rissoles.*—One pound of any cold cooked meat, one slice of bread, one large onion, one egg, seasoning, pepper, salt, and flour. Mince the meat, bread, and onion. Sprinkle with flour, add pepper, salt, and seasoning. Beat the egg and mix all together. Form into patties, dip in egg and bread crumbs, and fry for about 10 minutes. (Secretary, Mrs. E. Wall.)

GLADSTONE WOMEN'S (Average annual rainfall, 16.40in.).

February 13th.—Present: 14 members.

HOW TO RUN A KITCHEN.—Mrs. G. Smallacombe read the following paper, which was also read at the Wirrabara Conference:—Make a kitchen attractive; because it is a kitchen it should not be neglected, for it is the most important room of the house. The two most important things in running a kitchen are cleanliness and economy.

The kitchen is the central point of the housewife's energies, and if forethought is used in the kitchen outfit it will save much time and trouble. If cooking utensils and saucepans are hung or neatly arranged on shelves there is no losing a saucepan lid, to grovelling on the floor groping for a dish that has slipped right to the back of a wide shelf. Make sure everything you need is convenient. Have a towelrack or line handy, a slate or book with pencil attached ready to put down groceries as the tins and jars get low, in order not to miss anything next order day. Farmers usually get their supplies about twice a week, and if some article is missed it is of no use phoning the grocer to bring it around or even going to our neighbor to borrow. Have a place for everything and always keep it in its place, not in one cupboard or shelf to-day and another to-morrow. It saves a lot of time if plates and saucers are neatly packed in a Nile for each size, and basins, piedishes, &c., are better put away in sets instead of put in a cupboard anyhow, as is often the case, and then very often the one you want is at the back under something else, and by the time you have found it the time has gone in which the cake or pudding could have been half mixed. A good plan for cutlery if you use a drawer is to make apartments out of boxes—one for knives, one for prongs and dessert spoons, a smaller box for teaspoons. Have a string holder ready for pieces of string. String holders can easily be made in a novelty shape, making a kitchen ornament. Have a tidy place for all clean papers, also waste paper basket for scraps for fire lighters. On many farms meals are served in the kitchen, but that is no reason why the meal should not look just as attractive and tempting as in any dining room. A nice white tablecloth, a table centre, and a vase of flowers go a long way towards making the meal look dainty. Some people think that if the meals are eaten in the kitchen jam tins or bottles can be placed on the table, but that is a thing of the past, or it should be. Modern housekeeping demands that the strictest attention be paid to the selection of food and its use for meal preparation, simply because rising costs mean that the housekeeping purse is less and less elastic. Food that is purchased has to be used so that there is no waste whatsoever. Left-over foods which were in the past discarded or haphazardly used have now to be carefully conserved and fashioned into dishes which form principal courses at meal time. The careful housewife endeavors to plan two meals at once so that she can provide some, if not all, of the ingredients at one cooking. For instance, when cooking rice for serving with curry, rice pudding should be a suggestion for to-morrow's meal. Save all bread crusts and bake them, then mince or roll to crumbs ready for use. The crumbs will keep for months if put in glass bottles with airtight lids. *A Few Economical Recipes.—Eggless Pudding.*—Butter, size of an egg, 1 cup sugar, 2 cups boiling water, 2 cups flour, 1 teaspoon carb. soda, fruit to taste; steam three hours. *Jubilee Cake:* 1½ cups S.R. flour, 1 dessertspoon of butter, 1 tablespoon sugar, 1 cup sultanas, currants, and peel, 1 egg, ½ cup milk. Method—Mix dry ingredients together, add egg and milk. Bake ½ hour in moderate oven, while hot pour on icing mixed with milk. Sprinkle with cocoanut, serve with butter. *Chocolate Layer Cake:* 1 cup sugar, ½ cup butter, 2 eggs, ½ cup milk, 1½ cups S.R. flour, essence vanilla and cocoa to taste. When cold fill with vanilla filling and ice with chocolate icing. *Cooking Hints:* (1) Before turning a steam pudding out of a basin, leave it for a few minutes, and it will shrink. Loosen the sides carefully with a sharp knife, put the plate upside down over basin, give it a slight shake, and lift it carefully away. This is a sure way of serving a pudding. (2) When the oven is too hot for cakes the heat can easily be lowered by putting a basin of cold water in it. (3) If a little carbonate of soda is added to tart fruits when stewing less sugar is required. (4) It will be found that rice is the cleanest and best thing to clean vinegar bottles. Put a little rice in the bottle, add some clean water, and shake; then wash and rinse in usual way. (5) If enough water to cover the bottom of a saucepan is boiled in the saucepan before adding milk it will seldom burn. (Secretary, Miss J. Sargent.)

GOODE WOMEN'S.

February 4th.—Present: Seven members and three visitors.

TABLE SETTING.—Mrs. D. Fagan contributed the following paper and Mrs. Klau and Miss P. Linke gave a demonstration of table setting:—"There are a few general rules which apply equally to mansion and cottage. However simple may be the meal, and however coarse in texture the cloth, it should be clean, free from creases, and arranged smoothly with the centre fold forming a true line the whole length of the table. The knives should be clean, bright, and sharp, and the silver clean and well polished. After each meal all knives should be cleaned and made ready for use. All crumbs should be removed from the table with brush and crumb tray, and the cloth either left on the table, or folded on the table, instead of taking it off and shaking outside and then folded. With care, a cloth will be scarcely soiled at the end of a week's use. Tablecloths and table napkins should be of as good quality as means will afford, alike in design when possible. Table linen should be very lightly starched;

if made too stiff, the corners of the tablecloths, instead of falling in natural folds, stand out awkwardly, and the table napkins are unpleasant to use. When setting a table, a good rule is to allow about 2ft. for each person's accommodation. Where the table is large, a little more room does not matter, but on no account give less. It is usual to lay two large knives and forks, a fish knife and fork, and a soup spoon; other knives and forks are supplied with the plates for the different courses. The decoration of tables forms a wide field of work for artistic taste and skill. Young people should have their taste for arranging flowers encouraged and be allowed to assist in decorating the table. Care should be taken not to overload the table with flowers and ornaments. Where the means or the supply of flowers is limited, delicate ferns and other plants suitable for table use may be used, for they look, in many cases, as pretty as flowers, unless the latter be most tastefully arranged. Very often the effect is marred by too many colors being introduced. It is equally so by too many flowers being used. Each flower should have room to stand out, and each flower should be put in in the way it grows. If hanging ones be used, let them hang; if they naturally stand upright, let them be so placed to look natural. Glasses through which the stems of the flowers can be seen should be filled with water, but bowls or stands can be filled with moss or sand, in which it is far easier to arrange the flowers than in water. Table napkins can be folded into so many beautiful designs or shapes that anyone who has any taste can make a dinner table look wonderfully well." (Secretary, Mrs. A. Watson.)

KALANGADOO WOMEN'S (Average annual rainfall, 32.34in.).

February 14th.—Present: 15 members.

TANNING AND DYEING SHEEPSKINS.—Mrs. Dowdell read the following paper:—"Procure a skin which has just been removed from a sheep, cut off all very dirty parts, and if the wool is soiled and dusty wash in several lots of clear water. Get a large tub, bath, or small trough, warm about a kerosine tin of water, dissolve in this about 3ozs. of soap, and add enough cold water to cover the skin. Let the skin soak for 12 hours, rinse off the soapy water, then repeat the same process, and leave the skin again for 12 hours, giving it a stirring occasionally. Take care to rinse off all soapy water, using three or perhaps four lots of water; leave a while to drain. Melt 1lb. alum and 1lb. salt in a little water over the fire, add enough cold water to just cover the skin (about 1gall.); let the skin soak in this for 12 hours, continually stirring and rubbing in the mixture. See that the mixture gets to all parts on both sides of the skin. Then let the water drain out. *To Dye.*—Have ready two packets of dye, boiled and strained, then add enough water to cover the skin, getting the dye over the wool as evenly as possible. Leave in the dye for six hours, stirring occasionally, and leave to drain. Before the skin is dry spread on a table and rub into the back ½lb. alum

G RUBBING
THIS WAY & WITH THIS MACHINE
THE MONKEY GRUBBER

Is the unrivalled method of clearing land. Of special design, and constructed to give great power in a compact and portable unit, trees and stumps are pulled cleanly, leaving less roots and snags to run. A Rope Shortener, together with simple and complete sturdy rope fittings, make extra savings in time. Yields move up and costs come down.

ADELAIDE STOCKISTS—Australasian Implement Co., Colton Palmer & Preston, Harris Scarfe Ltd., McPhersons Pty. Ltd., South Australian Farmers' Union.

A PRODUCT OF THE JACK PEOPLE
TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

and $\frac{1}{2}$ lb. saltpetre, well mixed together and broken into a powder. As the skin dries work it up with pumice stone or a piece of brick until the skin resembles soft leather. When thoroughly dry, comb out the wool with a steel comb." (Secretary, Miss A. Kennedy.)

MILLICENT WOMEN'S (Average annual rainfall, 29.70in.).

January 16th.—Present: Seven members.

APPLE JELLY.—Mrs. Cassels tabled the following recipe for apple jelly:—Take as many apples as required—windfalls will do, as they must be green—and small ones are the best. Place in a preserving pan with a few cloves, and add enough water to cover them. When boiled to a pulp—do not stir—strain through a jelly bag, and to every breakfast cup of juice add three-quarters of a cup of sugar. Boil briskly until it jellies, then pour into jars. Mrs. Altschwager remarked that when making jams or jellies it was an economical plan to save what was skimmed off and use it later for sweetening pies and puddings. Mrs. Varcoe said she seldom skimmed the jam. By adding a small quantity of glycerine or butter to the jam a few minutes before removing from the fire the froth was absorbed in the jam, and did not make it at all cloudy. If butter was used, all water should be well pressed out before it was put in the jam. Mrs. Altschwager read some recipes for casserole cooking, which interested those present. The Secretary read a brief report of the half-year's work.

YEAST.—At the meeting held on February 20th, which was attended by 10 members, a discussion took place on "Yeast." Mrs. Hart said it was better to scald the hops for yeast; boiling tended to make the yeast a dark color and brought out the bitterness of the hops. Mrs. Varcoe agreed, but preferred to boil it for about a minute; boiling for a longer period gave the yeast a bitter taste that was passed on to the bread. Yeast in which all the ingredients were cooked could be kept longer. (Secretary, Mrs. W. Varcoe.)

NELSHABY WOMEN'S.

January 29th.—Present: 10 members and visitors.

POULTRY ON THE FARM.—Mrs. R. Noble read the following paper, which was also contributed at the Wirrabara Conference:—Poultry may be made a valuable sideline on every farm, more or less depending on the time one has available for attending them. Without very much attention one may get returns, but with a moderate amount of attention and hard work one is sure of good returns (even if it does not rain much). It is better to have, say, 100 good laying hens, well looked after, than 200 more or less allowed to look after themselves. So far I have found 100 enough for myself to manage with the rest of my work, but that just depends on what one has to do and the help available. It is advisable to have as good a house as one is in a position to build (so far my hopes have not been realised), one that is easily cleaned with as little harbor for tick as possible. Used motor oil applied liberally to all perches, cracks in wood, &c., is good for keeping tick down. Always procure the best stock you can to start with, and try to improve; do not introduce all kinds of strains and fresh breeds. Leghorns are outstanding layers; Black Orpingtons have put up some good scores. Personally, I would like to test one against the other for eating food before discarding White Leghorns. A good cross should prove profitable for table birds. Layers and table poultry need different methods, and should be run on separate lines. Green feed must be fed liberally, especially through the summer. It makes healthy stock and good eggs. Good grain is necessary. Cut out the grain and you cut out the egg yield. Supply also plenty of shell grit, cracked bone, crockery, and charcoal. You must have good quality eggs to hatch strong chickens. Do not hatch late chickens. Early autumn and early spring are the best and most profitable. You must have young birds to lay well through the winter months. Sell off all hens after the second year, excepting any very persistent layers. These, perhaps, would be better to keep, and cull more heavily amongst the younger birds. If the young birds are looking miserable and you feel disgusted with them, try what a few feeds of chopped raw onions will do. There is much talk of poor farm eggs; that difficulty should be easily overcome by gathering and selling often, and most of all by producing only infertile eggs for market. But is the farmer always to blame? Eggs are often kept in the stores for a considerable time. Also, I made inquiries in Port Pirie if they could give a penny extra for fresh infertile eggs; the answer was, "Why, their customers would not give the extra," so conclude that farms cannot be so bad after all. Anyhow, it is up to us for the sake of the egg industry of Australia to see that ours are marketed infertile, fresh, and of good quality. (Secretary, Miss A. Lawrie.)

PARILLA WOMEN'S (Average annual rainfall, 13.70in.).

February 8th.—Present: 15 members.

PICKLES AND SAUCES.—The following recipes were brought forward:—*Mustard Pickles*—Ingredients—3 large cucumbers, 3 cauliflowers, 2lbs. onions, 2lbs. young beans, 1 cup of flour, $\frac{1}{2}$ cup mustard, 1 cup sugar, 1 tablespoonful turmeric, $\frac{3}{4}$ oz. cayenne pepper, 2qts. vinegar. Method—Cut the cauliflowers in small pieces. Cut the cucumbers in halves, scrape out the seeds, and cut in small pieces. Skin the beans and cut in pieces. Peel the onions and cut in pieces. Lay them in a strong brine of salt and water over night. Take out and drain, put all into a lined saucepan with boiling vinegar, then mix the other ingredients with a little cold vinegar, and mix with the cauliflower, &c. Boil for a few minutes. *Worcestershire Sauce*.—1gall. vinegar, 2 cups golden syrup, 3 cups plum jam, $\frac{1}{2}$ lb. garlic, 2ozs. cloves, 2ozs. whole spice, 2ozs. ground ginger, 1oz. cayenne pepper, 1 cup sugar. Boil for one and a half hours, then strain. (Secretary, Mrs. Welden.)

PARRAKIE (Average annual rainfall, 14.52in.).

February 25th.—Present. Nine members and seven visitors.

The meeting was held at the residence of Mrs. Threadgold. An interesting inspection was made of the flower and vegetable garden, and the poultry and cattle.

A previous meeting was held on January 27th, there being present 10 members and four visitors. Mrs. Fernc read a paper, "Discipline and Training of Children." Mrs. Hamilton gave several useful recipes. (Secretary, Mrs. M. Cabot.)

PINNAROO (Average annual rainfall, 14.70in.).

Meeting held February 6th. Present: Mrs. Fewings (Chair) and 11 members. Mrs. Sands read a paper, "How to Conduct a Meeting." (Secretary, Mrs. F. Atze.)

WILLIAMSTOWN (Average annual rainfall, 27.71in.).

Meeting held February 4th. Present: 10 members and visitors. Mrs. Hammatt read a paper, "Bread Making."

ODDS AND ENDS FOR THE HOUSEWIFE.—A further meeting was held on March 4th, when Mrs. Hamilton presented the following paper:—"In preparation for the jam-making season it is a good plan to save all clean pieces of white paper. These should be cut up into covers of the desired size. When the time comes to seal down the jam pots, prepare a small quantity of starch in the same way as one would for starching lace curtains. With a clean rag or a small brush smear over one side of each cover with the starch. Place two of these starched surfaces together and tie them on the jars as tightly as possible. If the paper is very thin three layers can be used. When dry the covers will be like strong parchment and the preserve will keep good for a long while. *Borax Secrets.*—The average housewife fails to realise the importance of borax, in spite of the fact that it is an invaluable aid in the majority of domestic duties. In cases where soda is too powerful, borax may be used to soften water with absolute safety. It should be added to hard water when washing silk and wool; it not only softens the water but improves the appearance of the fabric. When making starch, add half a teaspoonful of borax to each tablespoonful of starch. This will impart a gloss to the starched articles and make the iron run smoothly. Borax provides an excellent means of cleaning painted and varnished wood. For this purpose dissolve two teaspoonsful of borax in half a teacupful of boiling water, and add it to two quarts of cold water. To remove tea and coffee stains, apply a little borax to the affected part, and pour boiling water through the material. It may be necessary to repeat this operation several times. Add one tablespoonful of borax to the water when washing hair brushes. In this way every trace of grease or dirt will be removed. Borax is a disinfectant, and if dissolved in a little lukewarm water will make a good eye lotion or throat gargle. If windows are very dirty, wipe them first with a damp cloth. Then wipe again with a cloth dipped in methylated spirits. No polishing is required. (Secretary, Mrs. A. Cundy.)

SOUTH-EAST DISTRICT.

ALLANDALE EAST.

Twelve members attended the meeting of October 31st, when a paper, "The Marketing System," was read by Mr. W. Laslett.

Nine members were present at the meeting held on November 25th. The subject, "Wool and Its Uses," was discussed. (Secretary, Mr. T. Earl.)

MUNDALLA (Average annual rainfall, 19.39in.).

Ten members and two visitors attended the meeting of October 8th, when reports on the Adelaide Congress were received.

Meeting held December 4th. Present: 12 members and three visitors. An instructive address, "Rust of Wheat," was delivered by Mr. L. Dinning. (Secretary, Mr. A. Ross.)

PENOLA (Average annual rainfall, 26.15in.).

Matters of timely and local interest were discussed at the meeting of the Branch held on October 6th, which was attended by seven members and visitors.

At a further meeting held on November 7th, attended by eight members, Mr. W. Clifford read a paper, "Preparing the Wool Clips." (Secretary, Mr. F. Hinze.)

TANTANOOLA.

October 4th.—Present: Eight members.

CLASSING THE CLIPS.—Mr. H. Hutchesson read the following paper:—To obtain the best price for his wool a grower must place it before the buyers in such a way that they can select their requirements and value correctly. This can only be done when buyers have even lines of wool before them. Mixing wools varying in quality and yields—sound and tender—can only result in loss to the grower, not only because it cannot be valued correctly, but also because it reduces competition, which is a big factor in securing good prices. To-day it is possible to have wool re-classed in various wool stores. I do not consider this the ideal way because it is not possible to blend wool grown in various localities and this, and the fact of the wool having been pressed, does not lend to a good appearance. Although not ideal, it is far better than making a hash of classing in the shed. If it is possible to class well in the shed, this, in my opinion, is the best place. The belly should be dealt with as soon as possible after it has been placed aside by the shearers. All stains should be removed. Classing of bellies is sometimes warranted, the decision resting mainly on cost of work and probable gain in price. In a clip of only hundreds, I would not favor classing bellies, providing the quality is fairly even. It is not wise to mix Crossbreds and Merinos. After the fleece is removed from the board, the board should be well swept to remove all locks and prevent them becoming embedded in the next fleece. **Skirting.**—The object should be to remove all wool that is inferior to the fleece. Usually in this district it is only necessary to remove the following:—A little wool from the breech, because of it being on the strong side and carrying a little stain (in the case of ewes), and sweat formations on armpits; and second cuts and any shorter wool from the head, necks, and backs do not, as a rule, need to be removed. **Rolling.**—Just a few inches should be turned in on one side and the fleece then brought over, the result is that when the fleece is rolled the shoulder is exposed. **Classing of Fleece.**—The object should be to make lines as even as possible, the main factors being quality, condition, soundness, and length, while the character, bulkiness, and color must also be considered. An objection is sometimes raised to detailed classing because it makes too many lines. A man that has 20 types of sheep deserves a little trouble. Surely if a man gives consideration to the value of his wool he will keep his flock fairly even. **Pieces** should be picked if quantity warrants expense. The same might be said of lamb wool. **Locks.**—Remove all heavy matter, it does not pay freight. **Pressing.**—Handle fleeces carefully, the wool looks better on show floor and catches the eye of the buyers. At cut out it is advisable to start pressing at top lines and go downwards, then any wool over a bale can be placed in a lower grade and thus save bag lots.

FIRE FIGHTING.—Meeting held December 6th. Present: Nine members. Discussing this subject, members thought that the district council should do something in the way of providing fire-fighting appliances. They accordingly appointed Messrs. M. Telfer, G. Altschwager, and the Secretary to wait on the council at its next meeting and see what arrangements could be made. (Secretary, Mr. H. Kennedy.)

UPPER-NORTH DISTRICT.**(PETERBOROUGH AND NORTHWARD.)****EURELIA** (Average annual rainfall, 13.06in.).

Meeting held October 1st. Present: Seven members. Mr. C. Phillis gave an account of an interesting trip to Lake Tinker, and reports of the Annual Congress were received and discussed.

Meeting held November 1st. Present: Mr. G. Hall (Chair), 15 members, and eight visitors. Members discussed the subject, "Poisonous Plants." (Secretary, Mr. E. Wall.)

MORCHARD (Average annual rainfall, 13.50in.).

Meeting held October 3rd. Present: Mr. H. Tilbrook (chair) and 12 members. Messrs. A. R. Long and R. McCallum debated the subject "Harvester v. Header" and delegates to the Annual Congress tendered their reports. (Secretary, Mr. H. McCallum.)

QUORN.—Meeting held October 8th. Present: 11 members. Officers were elected, after which an address, "Sheep on the Farm," was delivered by Mr. F. Lehmann. (Secretary, Mr. O. Noll.)

WARCOWIE (Average annual rainfall, 12.16in.).

October 9th.—Present: 15 members and 10 visitors.

Mr. C. McKenna, B.V.Sc. (Veterinary Officer of the Stock and Brands Department) delivered an address, "Common Ailments of Farm Stock."

POULTRY.—A paper on this subject was read at the meeting held on November 11th, which was attended by 16 members and 25 visitors:—"To make poultry a paying proposition plenty of time and considerable trouble is necessary in rearing, feeding, and looking after the birds. For egg production the White Leghorn is the best breed. The first essential is a netting yard with plenty of room to provide for exercise and small houses in which hens can lay. These should be white-washed all over to prevent tick. A small plot of lucerne will prove a valuable addition to the fowls' diet. Wheat, bran, and pollard mixed with a little salt is also good for laying hens. If rabbits are plentiful they can be cooked and fed to the birds. The Minorca is a good table fowl, and turkeys are generally in demand at Christmas. The Black Orpington is a very good layer and an excellent table bird. When breeding, old and young ones should be kept apart for the best results. Poultry should be set during the months of August and September. (Secretary, Mr. A. Crossman.)

WILMINGTON (Average annual rainfall, 17.63in.).

Reports of the delegates who represented the Branch at the Annual Congress were received and discussed at the meeting held on October 14th. On the following day, in company with the District Agricultural Instructor (Mr. E. L. Orchard) members and visitors made a tour of inspection of the crops of the district. (Secretary, Mr. H. Stevens.)

MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

BEETALOO VALLEY (Average annual rainfall, 23.50in.).

October 13th.

In company with Messrs. E. L. Orchard and J. B. Harris (District Instructors), 15 members and three visitors made a tour of inspection of members' farms and orchards. At the evening meeting Mr. Orchard delivered an address, "Hay and Hay-making." (Secretary, Mr. J. Halse.)

BELALIE NORTH (Average annual rainfall, 17.84in.).

October 25th.—Present: 12 members.

An instructive meeting took place when the subject, "Power Farming," was debated. Messrs. J. Atkin, H. Cummings, and A. Bray supported power farming while Messrs. F. Cummings, M. Warner, and E. Carmichael opposed it. The judges, Messrs. F. Carmichael and J. Collier decided in favor of the latter by 194 points to 169. (Secretary, Mr. E. Carmichael, Jamestown.)

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1931.

Eggs for Hatching and Day-old Chickens.

WHITE LEGHORNS ONLY. DELIVERY—JULY, AUGUST, and SEPTEMBER.

PRICES—

EGGS—10s. per Setting of 15 Eggs; Incubator Lots, £2 10s. per 100.

DAY-OLD CHICKENS—17s. 6d. per dozen, £6 per 100. Free on rail, Salisbury.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury.

C. F. ANDERSON, Manager.

GLADSTONE (Average annual rainfall, 16.40in.).

A well attended meeting of the Branch was held on November 21st, when Mr. H. B. Barlow (Chief Dairy Instructor) spoke on the subject, "The Dairy Act." (Secretary, Mr. F. Chick.)

MURRAYTOWN.—Meeting held November 1st. Present: Mr. B. Starr (Chair) and 12 members. A report of the Annual Congress was presented by Mr. F. Borgas. On November 12th members made a tour of inspection of the crops in the western portion of the district. Afternoon tea was provided at the residence of the Secretary, Mr. E. Pitman.

SNOWTOWN.—Meeting held October 11th. Present: 12 members and four visitors. Mr. K. Ashby read a lengthy paper, "A Comparison of the Tractor with Horses." (Secretary, Mr. A. Hocking.)

WANDEARAH.

Meeting held October 1st. Present: 13 members. Mr. J. O. Hatter (Dairy Instructor) delivered an address, "Dairying on the Mixed Farm."

A further meeting held on October 18th was attended by 10 members and six visitors. A report of the Annual Congress was presented by the chairman (Mr. W. Slater). (Secretary, Mr. J. O'Shaughnessy, Wandearah East.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

BRINKWORTH (Average annual rainfall, 16.01in.).

October 6th.—Present: 22 members.

Mr. R. Booth gave an instructive address, "The Improvement and Cross Breeding of Wheats." Mr. H. Snow reported on the Annual Congress.

On February 22nd Mr. E. Carlyon presided over an attendance of 18 members. Arrangements for the Annual Inter-Bureau Seed Wheat Competition were discussed. (Secretary, Mr. H. E. Ottens.)

EUDUNDA.—Mr. H. Michael presided over an attendance of 13 members and four visitors at the meeting held on October 13th. Mr. H. B. Barlow (Chief Dairy Instructor) delivered an address, "The Breeding and Rearing of Pigs." (Secretary, Mr. L. Duldig.)

LIGHT'S PASS.

October 6th.—Present: 33 members and visitors.

Messrs. J. Leslie, A. Chapman, and T. Roenfeldt reported on the Adelaide Congress. Mr. H. Scholz delivered an address, "First Aid to the Injured."

Mr. J. B. Harris (District Horticultural Instructor) addressed a meeting of 33 members on November 3rd on the subject, "Successful Fruit Growing."

PIGS.—Mr. W. Sporn read the following paper at the meeting held on December 1st, which was attended by 38 members and visitors:—"So far as breeds are concerned, I find the Berkshire is the best pig, although the progeny of the Berkshire crossed with a Tamworth or Essex are also good pigs for profit. The sty should always be kept clean, with plenty of straw, and the young pigs should also have a yard so that they can have plenty of exercise. The sow must be fed well to rear the litter, which should consist of from 10 to 12. Feeding with plenty of skimmed milk, with crushed oats or pollard, is a good food, although I prefer crushed oats to pollard. After the young pigs are three weeks old I advise feeding them separately; they are then old enough to learn to feed themselves. This should be done to prevent the sow from becoming low in condition. Feed young pigs on skimmed milk with barley that has been soaked in water for a day. When the piglets are six to eight weeks old, wean them; they are then old enough to feed themselves, and it will also give the sow a chance to pick up again. Should there be some small pigs in the litter, leave them with the sow for another two weeks or so. Great care must be taken to feed the young pigs well after weaning them; if they are neglected at this stage they will become stunted. Fed properly, they should be ready for the market as porkers in about four or five months. Pigs for profit should be sold as porkers; there is always a better demand for porkers than for bigger pigs. When taking pigs to market or transferring them to a different sty on a hot day, care must be taken not to over-heat them; they do not stand much handling on warm days, and die very easily if over-heated." Mr. W. Ahrens read an instructive paper, "Bee Keeping." (Secretary, Mr. C. Verrall.)

NANTAWARRA (Average annual rainfall, 15in.).

October 2nd.—Present: Eight members.

Mr. E. Hamdorf read an article, "Bots and Tetanus in Horses." Discussing the paper, Mr. Starkey said bots sometimes caused stoppage in the stomach and considered treatment expensive, unless the animal was a valuable one. Tetanus, he considered, was more prevalent in intensely cultivated countries rather than in Australia. Mr. C. Nicholls advocated rubbing a preparation on the horse's jaw to prevent bots from laying eggs there. Mr. Durdin lost a horse from bots, and gave the following remedy:—Starve horse for 48 hours and treat with a solution of sugar and oil. Mr. Herbert did not think bots were so prevalent now as seven or eight years ago, and spoke of information gained from the late Mr. Place when he conducted a veterinary school at Nantawarra some years ago.

Mr. E. Hamdorf presided over an attendance of eight members at the meeting held on November 6th, when an instructive paper, "First Aid," was presented by Mr. W. Starkey. (Secretary, Mr. N. Robinson.)

WASLEYS.

October 9th.—Present: 28 members and two visitors.

WEEDS AND FUNGUS DISEASES ON THE FARM.—Mr. C. Currie read the following paper:—"Weeds are often overlooked by the farmer and cause little or no concern, but they do directly and indirectly cause a considerable loss to the man on the land, for the following reasons:—(1) Robbing from fallow the moisture which has been placed in it by tillage. (2) The extra workings caused, which are of little or no value to the fallow, during certain periods. (3) Decreasing the value of seed wheat when infested with weed seeds. (4) Lessening the value of wool, because of the burry seeds of many weeds. Weeds on fallow are all robbers of moisture, and, with the exception of a little sheep feed, are little or no value, and even though the weeds be returned to the soil after they have been killed, they have used in the short period plant food which it has taken months to place in the soil. It is, therefore, desirable to destroy them before they grow to any large size, either by means of cultivation or sheep. They often prevent further cultivation, which is of particular value during the summer months, when it is often impossible and undesirable for the farmer to attend to the fallow on account of harvest. Weeds such as soursobs, dandelion, charlock, three-cornered-jack, vetches, &c., should be ploughed under at fallowing time, and little trouble will be experienced with them on the fallow afterwards. The complete destruction of the soursob is impossible, owing to its bulbing nature, but if well cultivated from time to time, when flowering, will keep them in check and prevent them from making more bulbs. Seeding operations should be carried out late in the season, after the bulbs have germinated, and if sown with a fairly vigorous growing variety of wheat they cause little damage. Land infested with vetches should be treated in the same manner. Cattle and sheep do not eat them very readily when green, and if the crop is sown before the seeds germinate they check the growth of the crop during wet periods. The worst weeds in the district are wild mignonette, three-cornered-jack, and mustard. Every precaution should be taken to destroy the mustard and wild mignonette, the crop cannot be reaped without getting the seed in the grain, and any plants should be pulled and destroyed before they reach the seeding stage. Summer weeds, such as paddy and wild melon, stinkwort, potato weed, artichoke, and buck-bush, &c., are best destroyed (if too large an area is not too infested) with a hoe or grubbing axe, because no harm is done to the fallow; but if a large area has to be treated, the blade attached to the cultivator, or (if the land is too stony for its use) wide shares can be used with good results, and little damage is done to the fallow if worked shallow and is done after rain. *Noxious weeds.*—It should be the aim of every inhabitant of a district to destroy all noxious weeds. When a new variety is seen it should be destroyed, for often a few weeds are the means of spreading seed over a large area. Bathurst burrs and star thistles should be destroyed prior to flowering; if cut when gone to seed they blow about with the wind, scattering the seeds worse than if they were not cut. *Wheat Diseases.*—Many of the diseases common in cereal crops can be checked considerably by keeping the fallow free from wild oats and barley grass. Stubbles of crops which have been affected with diseases should be burned; if ploughed in they have a tendency to affect the crop following it. Take-all can be considerably overcome by good fallowing methods and a system of crop rotation, which places the land in such a good condition as to be able to ward off this and many diseases from the young plant. Trouble can be minimised if wheats immune from many of the worst diseases are sown, such as Nabawa and Sword, which are flag-smut resisting. Care should be taken when purchasing seed grain from other districts that no foreign weed seeds are contained in it, many bad weeds are spread about through not taking this precaution. If seed is not badly affected with bunt, copper carbonate at the rate of 1oz. to 2ozs. per bushel is the best method of control, but if badly affected I favor sprinkling the grain with a

solution of formalin at the rate of 1lb. to 60galls. of water, and for barley 1lb. to 40galls. of water. If the seed is too badly affected with bunt, do not use it for seed purposes—prevention is better than cure.”

A combined meeting of the Women's and Men's Branches was held on January 8th, when Mr. H. B. Barlow (Chief Dairy Instructor) delivered an address, “The Dairy Act.” (Secretary, Mr. C. Currie.)

ROSEWORTHY.—Meeting held October 13th. Mr. A. R. Hickinbotham, B.Sc., Dip. Ed. (Chemist, Roseworthy Agricultural College), delivered an address, “Chemistry as Applied to Agriculture.” (Secretary, Mr. E. Oates.)

YORKE PENINSULA DISTRICT.

(TO BUTE.)

ARTHURTON (Average annual rainfall, 16in to 17in.).

Meeting held October 30th. Present: Mr. J. Hentschke (Chair), 15 members, and five visitors. Mr. R. Burns read a paper, “Economy on the Farm,” and reports of the delegates who attended Congress were received and discussed. (Secretary, Mr. T. Howlett, Moonta.)

KILKERRAN.

October 7th.—Present: 14 members.

CONSERVATION OF FODDER.—The following paper was read by Mr. B. Koch:—“This is a matter which concerns every farmer, especially in time of drought. A good standby is a stack of sheaved straw, which should be cut in a good season. A stack of loose straw is also very helpful for stock that are not working. If a quantity of salt is added to the straw the stock will eat it much better and they will not be so liable to constipation. Oats is a very good fodder, and the grain can be stored for a very long time without being spoiled by weevil. If stored loose, mice and rats will not damage it. Oats are an excellent ration for fattening sheep when other paddock feed is scarce, the stock will not eat so much chaff. Chaffed straw and oats with a little molasses added makes very good feed in time of drought. Where much stock is kept a good haystack should always be held in reserve. This should be surrounded with a mice-proof fence and covered with a thatch of straw. Farmers should always conserve a certain amount of fodder, it is cheaper to produce fodder than to buy same, and if conserved when cheap the amount saved on drought prices will easily pay the interest on the outlay. Storing oats can be done by making a compartment in a shed, then, if it is desired to leave some in bags, place a layer of bags on the bottom then fill all space with loose oats. This will take about as much loose oats as if they are bagged, therefore a space large enough to stack 50 bags of oats in bags will hold about 100 bags. When all the space between the bags are filled, and a layer of about 6in. placed on top, it will prevent mice getting at the bags.” Mr. B. Koch read a paper, “Harvest Machinery.” (Secretary, Mr. A. Dutschko.)

PASKEVILLE (Average annual rainfall, 15·64in.).

Seventeen members attended the meeting held on October 7th, when delegates to Congress gave reports of papers, &c., read at the various sessions.

A lecture was delivered by an official of the Royal Automobile Association at the meeting held on November 4th.

A further meeting attended by 17 members and four visitors was held on February 3rd. Mr. H. Price read an instructive paper on “Fencing.” (Secretary, Mr. J. Prouse.)

PETERSVILLE.

October 7th.—Present: Nine members.

HARVEST PREPARATIONS.—Mr. K. Wood read the following paper:—“Prior to the commencement of harvesting operations all machinery that is to be used should be thoroughly overhauled and placed in good working order. As it is the aim of every farmer to take off his crop in as short a period as possible, this is important. The binder should have all old grease removed from its bearings, rust cleaned from the retainer and knoter, bolts and chains tightened, and the canvasses inspected to see that straps are fixed securely. Straighten up fingers and sharpen the knife. Cut around the crop and plough firebreaks. When hay cutting is finished, take off canvasses, roll up, and put away out of reach of rats and mice. In the case of the harvester, adjust comb thresher, clean and tighten bearings; if belts are used, give a good dressing of Neatsfoot oil. Examine chains for worn links, and put fresh wicks in the oil wells. Where a tractor is used, remove cylinder head, clean out carbon, &c., have an efficient spark arrester fitted to the exhaust to minimise the risk of fire.

If using horses, have them shod, give all harness an oiling, and see that all swings and chains are in good order. Have plenty of bags and oils on hand. If this is done very little time should be lost during harvest." Mr. Duke reported on the Adelaide Congress.

Under the auspices of the local Branch a meeting was held in the Ardrossan institute on November 4th, when Mr. Crewe, of the Vacuum Oil Company, gave an address illustrated with moving pictures, "Oil and Its Products." (Secretary, Mr. A. G. Dutschke, Ardrossan.)

SOUTH KILKEBBAN.

October 7th.—Present: 12 members.

Matters relating to the barley experimental plots were discussed. During the afternoon of November 3rd 12 members and 12 visitors, accompanied by Mr. R. Hill (District Agricultural Instructor) inspected the barley experimental plots. In the evening Mr. Crewe, of the Vacuum Oil Company, delivered an address, "Oil and its Products."

HARVEST REPORTS.—At the meeting held on February 3rd, which was attended by 10 members, it was reported that yields for the 1930-31 harvest would not exceed 12bush. to 15bush. Best varieties were Sultan, Phoenix, Ford, and Waratah. Barley averaged 15bush. (Secretary, Mr. H. Schrapel.)

WEAVERS (Average annual rainfall, 17.03in.).

Meeting held October 18th. Present: 13 members and two visitors. Mr. R. Hill (District Agricultural Instructor) delivered an address, "Conservation of Fodder."

Addresses on phases of the dairying industry were delivered by Messrs. H. B. Barlow and H. J. Apps (Department of Agriculture) at the meeting held on October 20th; 16 members and 11 visitors were present. (Secretary, Mr. H. Cornish, Stansbury.)

WESTERN DISTRICT.

CARALUE.—Meeting held October 8th. Present: 17 members and 45 visitors. Mr. R. Jones gave an address, "The Foot of the Horse," and Congress reports were received. The meeting then took the form of a social evening. On October 13th Mr. W. J. Spafford (Deputy Director of Agriculture) addressed a meeting, which was attended by 15 members. (Secretary, Mr. E. Marshall.)

GREEN PATCH (Average annual rainfall, 26.56in.).

October 2nd.—Present: 10 members.

The meeting was held at the residence of Mr. C. J. Whillas. Reports were received from delegates who represented the Branch at the Annual Congress.

Mr. E. Chapman presided over an attendance of 12 members at the meeting held on November 13th, which was held at the residence of Mr. P. Sinclair. Matters of local interest were discussed.

Members met at the residence of Mr. T. Murray on December 4th, when Mr. H. D. Adams (Agricultural Instructor) delivered an address, "The Fat Lamb Industry." (Secretary, Mr. C. J. Whillas, Port Lincoln.)

MEGGITT'S LINSEED MEAL.

The seasonal reduction during certain months of the year in the output of milk, cream, butter, and cheese, can definitely be checked by the use of Meggitt's Linseed Meal.

Meggitt's is a highly concentrated food, rich in essential milk producing and body building protein, and conditioning linseed oil in the correct proportions.

Sold in any quantity, from one big (100lbs.) upwards.

Obtainable from any Dairy Produce Factory, Grain or Chaff Merchant, or direct from—

ELDER, SMITH, & CO., LIMITED,
SELLING AGENTS IN SOUTH AUSTRALIA.

KAPINNIE. October 14th.

Mr. J. Lawrence presided over an attendance of 23 members and 21 visitors. Addresses were delivered by Messrs. W. J. Spafford and H. D. Adams, of the Department of Agriculture.

During the afternoon of November 21st the annual inspection of crops took place. The evening meeting, which took the form of a social, was attended by 24 members and 50 visitors. (Secretary, Mr. E. Wannon, Brimpton Lake.)

MANGALO (Average annual rainfall, 14in. to 15in.).

October 6th.—Present: 12 members.

The meeting discussed important matters relating to the stacking of 1930-1931 harvest at Mangalo.

Meeting held November 3rd. Present: 11 members. Mr. F. Coll reported on the Adelaide Congress and the Kimba Conference. (Secretary, Mr. C. Hannemann.)

MINNIPA (Average annual rainfall, 14.68in.).

Meeting held September 30th. Present: 12 members. Mr. J. Head gave a report of the Annual Congress. (Secretary, Mr. F. Williams.)

MUDAMUCKLA.

October 11th.—Present: 13 members.

Mr. W. H. Watson read a paper, "Working Up and Putting In a Crop on Old Land at Seeding Time." He considered breaking up the land with a cultivator and then drilling in with the combine, followed by the harrows a few days after combining, to be the best method. A good discussion followed. Mr. Maquire, as delegate to Annual Congress, gave a report of the proceedings of the Annual Congress. (Secretary, Mr. T. Zippell.)

PETINA (Average annual rainfall, 13.02in.).

Meeting held September 23rd. Present: Mr. W. Schulz (Chair) and 13 members. Several matters including the advisibility of continuing the crop competitions, were discussed. (Secretary Mr. E. Jones.)

PYGERY.

October 7th.—Present: 24 members.

An instructive paper, "The Production, Cost, and Price of Wool," was read by Mr. L. Humphries. Congress reports were received and discussed.

SCRUB CLEARING.—A paper on this subject was read at the November 4th meeting by Mr. B. Ingram:—"The most popular method is the scrub roller. The roller is usually an old steam boiler with an axle through the centre and a frame built on or over the top. Usually for a horse team the roller is built with the frame over the top, with a pole and wheel in front and a breaker bar 6ft. to 8ft. high. With a tractor, the frame may be on a level with the axle and no wheel in front, but connected straight to the tractor. *Logging.*—The log is usually about 10ft. to 12ft. long, with two teams or tractors to drag it along. Some logs are built with a frame and breaker bar. Usually two teams or tractors are used to draw it along, but one tractor may be used in light scrub. The scrub devil is a high frame on two stout wheels, with a pole and front wheel. It is usually built after the style of the scrub roller, but the pole may be placed in the centre and the tractor go through the scrub. The scrub devil is used in heavy timber where it would be difficult to use a roller or log. It would be advisable to hire axemen in scrub that has been heavily timbered and burnt and consists of young trees about 15ft. high, as it is very rough on team or tractor. The scrub in this district may be classified as follows:—First, the heavy timber that is anything over 20ft. high; second, the medium scrub, anything from 10ft. to 20ft. high; the third and easiest to clear is the light bush below 10ft. in height. The tractor is the best for clearing scrub; it saves time, and there is not so much nicking to do as with a horse team. For a person taking up a scrub block a tractor would be best, as there is no water to cart. All that is needed after the scrub is knocked down is a good fire. Felling that, stick picking has to be done." A further meeting held on December 2nd, attended by 25 members, took the form of a Question Box. (Secretary, Mr. A. Day.)

ROBERTS AND VERRAN.

October 8th.—Present: 15 members.

An instructive paper, "Harvest Preparations," was contributed by Mr. V. Jonas.

MARKETING WHEAT.—The following paper was read by Mr. F. Imhoff at the meeting held on November 5th:—"In the preparation and marketing of wheat the sample should be free from all foreign matter. One of the failings of many Australian farmers is to sell wheat containing all sorts of rubbish, and to command the best price

and demand is an object which should be aimed at. If buyers in the overseas markets were sure of a good clean sample there would be a greater demand for our wheat. Varieties most suitable for foreign markets, wheats to blend with the red wheats of other countries, should be grown. Bulk handling would reduce the cost of handling and shipping and help to create a better price. At the present time there are only two ways of disposing of wheat: one by way of selling it to the wheat merchant, a system which has stood the test of many years; secondly, by the pooling system. Until all farmers support it, the pooling system cannot be worked to its full advantage, and by working in with the pooling systems of other countries the full benefits will be gained." Discussing the paper, Mr. M. Masters advocated selling wheat by grades instead of on a f.a.q. basis. Mr. J. Smith said that while bulk handling that would be costly to install, it would result in a reduction in handling charges. Mr. H. Mahar stressed the importance of the need for using a grader and only sowing the best and cleanest seed. Messrs. S. Barber and P. Busche spoke in favor of pooling. Messrs. E. Pobke, L. and H. Ramsay, C. Masters, L. Gordon, and J. Busche also spoke. (Secretary, Mr. C. Masters.)

TALIA (Average annual rainfall, 15.27in.).

Mr. F. Elliott presided over an attendance of 18 members and two visitors at the meeting held on October 11th, when addresses were delivered by Messrs. W. J. Spafford and H. D. Adams, of the Department of Agriculture. (Secretary, Mr. A. Thomson, Elliston.)

WIRBULLA.—Meeting held September 25th. Mr. F. Lovegrove presided over an attendance of nine members and six visitors. A paper, "Horses v. Tractor," was contributed by Mr. J. Pearson. (Secretary, Mr. H. Doley.)

WUDINNA (Average annual rainfall, 13.68in.).

October 3rd.—Present: 13 members.

FARM ECONOMY.—A paper on this subject was read by Mr. A. Shepherd. In the discussion that followed Mr. Hollams favored borrowing money from the bank to purchase implements rather than buying on the time-payment system. Matters of local interest were also discussed.

Meeting held November 1st. Present: Nine members and six visitors. Reports of the Annual Congress were received and discussed. Mr. C. Newbon gave an address, "The Clydesdale Horse."

A meeting held on December 23rd was attended by eight members. Matters in connection with the Crop Competitions for 1930-31 were discussed (Secretary, Mr. C. Newbon.)

YADNARIE (Average annual rainfall, 14.09in.).

Meeting held October 14th. Present: 10 members. Mr. M. Way read a paper, "Grading Wheat for Export". A keen discussion took place on the subject. "Side Lines on the Farm" (Secretary, Mr. C. Deer, Cleve.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

ALAWOONA.—Accompanied by the District Agricultural Instructor (Mr. R. L. Griffiths) 13 members of the local Branch and 25 visitors from the Caliph and Veitch Branches inspected the plots on the Veitch Experimental Farm, under the guidance of the Manager, Mr. L. Smith. (Secretary, Mr. B. Finly.)

BRINKLEY.

Meeting held October 9th. Present: 18 members and two visitors. Congress reports were received and discussed.

Twenty members and four visitors attended the meeting held on November 5th. Matters of local interest were introduced for discussion. (Secretary, Mr. C. Pearson.)

COPEVILLE.—Meeting held October 15th. Present: 12 members. Reports of delegates to Annual Congress were received and discussed. On November 18th a large number of members and visitors, in company with Mr. R. C. Scott (Superintendent of Experimental Work) inspected the plots being conducted on the property of the Secretary (Mr. G. Sutherland).

CLANFIELD (Average annual rainfall, 16in. to 17in.).

Meeting held October 16th. Present: eight members. Mr. L. Orwell read a paper, "The Chamber of Rural Industries," and reports of the delegates to Congress were received and discussed. (Secretary, Mr. W. Pearce.)

KALYAN.

October 15th.—Present: Eight members.

CARE OF THE BREEDING EWE AND MARKING AND TAILING LAMBS.—Mr. R. Lang presented the following paper:—When financial difficulties and bad times confront the producer, more precautions should be taken with the flock. Bad seasons have made sheep-breeding more difficult these last few years. That is the time when breeders should provide better management of the flock. The flock should be inspected every day, to see that the sheep are all right. Breeding ewes should receive first consideration. It is advisable to keep the breeding ewes in a separate paddock. The flock should be mouthed, and faulty and weedy ewes culled out for rations or fattened and sold. Mouth the ewes just after shearing, and after lambs have been weaned. It does not pay to breed from an old ewe. She is never in such good condition as a younger ewe, nor is she so able to stand the strain of rearing a lamb. The best ages of ewes to breed from are from a 4-tooth to a full mouth. When mouthing and culling, only the best, youngest, and strongest ewes should be kept for breeding. The ewes chosen for breeding should be put in a good paddock, separate from the other sheep, and the rams put with them. Rams should never be put in any later than early December. This will procure an early lamb, which will be well grown in the spring, when feed is good. The ram is just as important as the ewe; the ram must not be too old, and should be in as good a condition as the ewe. After the rams have been mated with the ewes, they should either be frequently yarded or mustered into a small paddock over night. This will give a better lambing percentage and more even lambing. This should be done for the first five or six weeks after the rams have been put in. During the mating season the ewes should be allowed to graze on good pasture. This will give a good percentage of lambs. The ewe will be strong and in good condition, and will rear a good lamb. A month or five weeks prior to lambing the ewes should be got in, crutched and wigged, and the rams removed from the ewes. Crutching gives the lamb a better chance of finding the teats when it is young. It also minimises the danger of the ewes getting flyblown after lambing. When crutching the ewes, do not handle them roughly, otherwise losses may be expected. When the lambing season commences the ewes should be inspected once a day, to see if any of the ewes are down or need attention, and if any of the ewes that have lambed have left their lambs. All dogs should be kept out of the lambing paddock. A good plan, if it is possible, is to shift the ewes with the strongest lambs from the lambing paddock to a fresh paddock. This can be done after the lamb is about a week old. A little time spent in this direction is well worth while. Changing the ewes and lambs from one paddock to the other where feed is better enables the ewe to give more milk and the lamb will grow stronger and faster. On no account should a ewe with a lamb be placed on dry feed. If drought conditions prevail and hand feeding has to be adopted, the ewes should be given such food as will make milk for the lamb; otherwise it is just as well to sacrifice the lamb to save the mother. Before tailing operations commence, all yards that are going to be used should be cleaned out and all refuse carted away. If tailing operations are performed with a knife, it should be well sharpened and sterilised before it is used. The day of tailing should be of moderate temperature, operations should be started early in the morning, and sufficient hands available to finish by about 3 o'clock in the afternoon. This will give the ewe time to mother her lamb before darkness sets in. An inspection should be made of the flock to see that everything is all right, because if the next day is sultry or hot, some of the lambs may have been affected by flies or need attention in some other way. The flock should be left to settle down for the first two or three days before driving or shifting any great distance. Tails, &c., should be cleared out of the yard and either burnt or buried. Finally, sprinkle the yard with disinfectant, such as milk oil fluid, and leave the yard fresh and clean for the next time it is to be used." (Secretary, Mr. R. Lang, Goondooloo.)

LAMEROO (Average annual rainfall, 16.19in.).

October 10th.—Present: 13 members and two visitors.

The District Agricultural Instructor (Mr. R. L. Griffiths) delivered an address, "Factors Controlling Wheat Yields in the Mallee."

SHEEP ON THE FARM.—The following paper was read by Mr. R. Pocock at the meeting held on November 22nd:—It is recognised that for the successful cultivation of wheat, sheep play an essential part on the farm. With costs of wheatgrowing continually mounting up, it will be readily seen that for the capital laid out the margin of clear

profit will be greatly in favor of sheep. At this period in our history, when every effort is being made to make our country pay its accounts overseas—wool and meat being commodities that are relatively cheaply produced—farmers must devote more attention to wool and fat lambs. It can be said with as much truth as ever that “Australia is carried on the back of the sheep.” In our district, which is essentially a wheat area, for profitable management the farm is most efficiently worked on a system which allows wheat to be grown once in every three years, thus allowing one year of feed off stubble land. In the first place, the wheat crop will do better and the land be kept in a more vigorous condition. To keep fallow in good condition on land that has previously laid out, extra working of the fallow is practically essential. These workings are reflected in the crop of wheat. The management of the sheep may be divided into the following headings, and in certain conditions either method may be made profitable:—(1) Merino flock kept entirely; (2) pure bred Merino ewes mated with English rams; (3) Cross ewes of Merino formation with English rams; (4) pure bred English breeds. Merits of each breed as it applies to this district:—(1) The pure bred Merino flock is only practical on a large holding and where hand feeding is not the general practice and aims at the production of ewes for sale and wethers. In a flock of this description about half of the flock is readily saleable, leaving the breeding flock of ewes to be kept in times of poor seasons. Some flocks of this description are very valuable in a district, for from them good lines of ewes are available, but as a general practice, this method of sheep keeping cannot be considered as most useful here. (2) Merino ewes mated with English rams.—For general practice, the large-framed, clean-faced, and active Merino is a sheep hard to beat for the production of fat lambs for market. As time goes on these sheep will be more difficult to procure. Farmers generally will find that money is well spent in paying for a good class of young ewe. At the recent large sales in the north it was noticeable that for short yardings of 2-6 tooth ewes good values were paid for them. This is rightly so, because the fleeces grown give a fair margin on the amount paid for the sheep. Also these sheep will be useful on the farm until six years old. There is a wide selection of rams to mate with these sheep, but it is generally recognised that the Down breeds of sheep are the best for the production of a lamb for the English and local markets, i.e., a lamb whose live weight is 64lbs. to 70lbs. and dresses 32lbs. to 38lbs. My choice of rams is the Southdown, Shropshire, or Suffolk. Mated with pure Merino ewes, these sheep give more block formation of carcass and mature early. The Dorset has found great favor, but, nevertheless, they do not, as a general rule, fulfil the requirements of the short, compact carcass so necessary for export. (3) Cross bred ewes as a flock mated with English rams.—I also include the Corriedale under this heading, for it is generally considered a crossbred sheep. This method of lamb raising is a good one, and it will be noticed that in the awards of prizes to fat lambs at the most important shows the crossbred ewe is usually responsible for raising the first prize lambs. They mature early, grow quickly, and the ewes are much better milkers. Thus the lambs are more sappy and presentable at the bloom stage when a lamb is marketed. The production of lambs from these ewes is generally fitted for the districts where the rainfall is a little better than in the mallee; at least this is generally recognised. From personal observations I see no reason why the crossbred ewe could not be kept. They do well at home and also on other people's feed, and the latter point I suggest as practically the only serious disability. The wool of these sheep brings good money—as much per lb. as the Merino—but weights are not equal to Merino. This type of ewe for fat lambs will be used more extensively. (4) The use of pure English breed.—This is not an especially good method for raising fat lambs; the sheep are sluggish and do not mate quickly and it is difficult to obtain a line of early lambs from pure ewes. Merino and Merino cross ewes are much quicker and less trouble, therefore, for general purposes, this method is of little interest. Points worth bearing in mind.—Do not try and breed from ewes that are too young, or mortality will be heavy where English rams are used. Always obtain clean-faced sheep when buying replacements. Do not cut tails too short when marking lambs; this increases fly trouble. Machine crutching is practically essential, and, if possible, should be done about four to six weeks after shearing, and again in March. The expense of this practice will be overcome by the use of small plants used by several owners. I suggest that a class for fat lambs be included in the local show; live weight to be 62lbs. to 70lbs, and judged for the best turned out lamb at the weight. Hand feeding of sheep for market is not a payable proposition and may be done only in a moderate way with lambing ewes and stud stock. Another reason is that in times when it is necessary to feed, sheep are forced on the market and one is usually found feeding food, which is gradually rising in price to sheep, the value of which is getting cheaper. It is better to keep a few less sheep and save the worry for some one who will buy your reserve fodder. (Secretary, Mr. R. Koch.)

MARAMA.—Congress reports by Messrs. Rogers and Hinkley were received and discussed at the meeting held on October 29th. Fifteen members were present. The meeting held on November 15th was attended by 15 members. Mr. T. Hinkley (Hon. Secretary) read a paper, "Wool."

MILLENDILLA.—Meeting held October 2nd. Present: seven members. Mr. B. Scheer spoke on the subject, "The Farmers' Freedom Association." (Secretary, Mr. V. Wegener.)

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

October 18th.—Present: 14 members.

FARM BLACKSMITHING.—Mr. M. Kuchel read the following paper:—"A blacksmith's shop on the farm will save many a trip to the township and loss of time in repairing breakages which are inseparable from cultivator and harvesting work. At periods which are not busy on the farm, odd jobs can be done and old material which would otherwise be thrown on the scrap heap can be used in making handy appliances for farm operations. The shop should be equipped with a forge, anvil, vice, drilling machine, some tongs, a couple of hammers of different weights, a sledge hammer, an assortment of punches and chisels, wrenches and spanners, a set of taps and dies suitable for threading all sizes of bolts from $\frac{1}{4}$ in. up to 1 in. in thickness. With these tools a farmer can do numerous jobs, such as making eyebolts, S hooks, split links, sharpening ploughshares, crowbars, picks, &c. In welding it is necessary to keep the fires and irons to be welded clean and free from clinker. The iron should be heated to a white heat. Old tyres from a buggy or spring-dray can be made into very good gates. In preparing to weld two pieces of iron, see that both reach the proper heat at the same time. Heating should proceed smoothly and gradually. Share sharpening is one of the most important jobs on the farm, and requires a certain amount of skill. Do not overheat or burn the shares; draw the metal down to a fairly long edge and see that the share is perfectly level and straight on the bottom. Broken set-screws in pulleys or cogs may be removed by sawing a nick across the set screw, then if the set-screw will not move with a centre punch, bore a small hole so that a larger drill will follow through the set-screw without running into the casting. A few carpenter's tools and a soldering outfit will also add to the usefulness of the equipment. Many kinds of fluxes can be used for soldering, but 'killed' spirits of salts will solder tin or galvanised iron. To kill spirits of salts, place a small quantity of the spirits in an open-mouthed bottle, add a few pieces of zinc, and when the spirits have finished boiling, remove the zinc which has not dissolved and add one-third of rain water and a few shavings of sal ammoniac. In handling spirits of salts be careful that none touches the hands, as it is apt to be very painful; also see that none gets on the clothes. See that the iron is well tinned and clean. In tinning an iron, heat to soldering heat, then polish with an old file and rub in a piece of sal ammoniac into which a piece of solder has been dropped. See that all tools are in a handy position, so that they can be found without any trouble. Have a place for everything and keep everything in its place."

BOOKKEEPING.—Mr. V. Lehmann read the following paper at the meeting held on November 15th:—"Present indications point to the fact that it is likely to become increasingly difficult for the farmer to make a living unless he can find means for reducing costs of production. It is unlikely that there will be any very great increase in the price which his commodities bring, therefore it is our duty, if we are to succeed through this depression, to keep a correct account of all matters which our farms produce. If we know certain lines are not paying, we should at once investigate every possible way of making economies. The achievement of this can be accomplished in various ways, and is mostly within the power of each individual farmer. Improvements and innovations which tend to improve farming methods are constantly being introduced, and to be truly efficient the farmer must keep ever in line with these. To be able to run any business, and at the present time farming is as much a business as any other line of production, the proprietor must have some means of analysing his various costs and of telling where and how his methods need revision or elimination. Every farmer should have some method of bookkeeping which will enable him to know what lines are and what lines are not proving economical. Unless he knows this, it is practically useless to attempt any improvement in his income. Farm bookkeeping is a complicated business and not to every farmer's taste, but the need for it is becoming increasingly great. There are very few farmers in a position to state definitely what their actual costs are, for they do not keep records of their operations or of the results obtained. Records can be kept provided one is prepared to go to some trouble and exercise care. Some knowledge of accountancy is required to assist one in the keeping of such records to determine the cost of different operations, such as tractor and horse maintenance, harvesting, and seeding, also of a much neglected item: depreciation. Few farmers have had the opportunity of acquiring a grounding in proper bookkeeping methods, and after a long and laborious day's work in the field, sitting down to bookkeeping at night is almost out of the question. With the demand of the Taxation Office, due attention to the

keeping of records is necessary. For his own financial wellbeing the farmer should know at the end of the year how and in what direction his business progressed or not. In short, each year he should have a stocktaking. A properly prepared statement will aid him in avoiding or discontinuing various lines that do not pay, and possibly the extension of those things that would pay for more attention, also whether he is putting his energy to the best use. One of the first essentials to keeping of records for the farmer is a full-sized diary and a properly-kept daybook. Once or twice a week the farmer can write up what he has done on each of the intervening days, what he has paid out, what he has received, also records of weather and rainfall if so desired. It should show dates of fallowing, seeding, and harvesting results, with kinds of wheat, etc., stock bought and sold, periods of lambing, numbers of sheep shorn, bought, or sold, and each succeeding year will become a valuable book of reference. As regards finances, periodically the farmer can go through it, and from it enter up in a ledger, which is essential, all receipts and payments. With the diary for reference, matters are simplified for taxation purposes. The farmers' receipts can be reckoned easily as a rule: so much for wheat, hay, stock, cream, eggs, and so on; but in the matter of outgoing monies he is likely to overlook much that could and should be recorded as legitimate expenses. The farmer pays cash for many items, and these should not be forgotten, because in the course of a year they may run into pounds, but if entered in the diary or daybook they can all be totalled at the end of the financial year. When dealing with the ledger, more care is necessary, for the headings should conform as far as possible to the headings in the taxation returns. There should be headings for everything on the farm, including all kinds of livestock, each separate, so that gains or losses can be recorded for each. Then there are poultry, machinery, implements, harness, tools, fencing, sheds, &c., and all the activities of the farm, not forgetting insurance against fire, workmen's compensation, accident insurance, &c. At the end of the year all the balances taken from the ledger should balance with the bank passbook, if all amounts received have been paid in and cheques drawn for all debits. There is still another item to be taken into account, and one in regard to which farmers are prone to overlook, that is depreciation. In reading a business balance-sheet the line 'written off' is frequently observed. It cannot be denied that so soon as buildings, fences, &c., are erected, decay, not noticed perhaps for a long time, sets in, and the same applies to machinery, harness, tools, etc., after a certain age is reached. Depreciation, therefore, should not be omitted from the balance-sheet, and farmers should make reasonable allowance for depreciation of plant and improvements when estimating their income for the year. In justice to himself, and those dependent on him, the farmer should protect himself by keeping a strict account of all his transactions."

WHEAT SAMPLES.—Thirty-seven samples of wheat from the past harvest were tabled at the meeting held on January 24th. These ranged from 55lbs. to 65lbs. to the bushel, with an average of 65 1/7th lbs. approximately to the bushel. (Secretary, Mr. C. Altmann.)

MYPOLONGA.

Meeting held September 24th. Present: Nine members and seven visitors. Mr. P. Collins read a paper, "Unit Values of Manures." Certificates won in the 1930 Pruning Competitions were presented, and reports of delegates to Annual Congress received and discussed. (Secretary, Mr. P. Pickering.)

MOORLANDS (Average annual rainfall, 14.76in.).

October 29th.—Present: four members and four visitors.

CONVERTING A SCRUB BLOCK INTO A FARM.—Mr. W. Coombe read the following paper:—"First choose a site for the homestead, which should be on rising ground, as near the centre of the block as possible, so that all paddocks will open into one home paddock, and if the section is square, this is quite feasible. It also makes it possible to have water laid on to all the paddocks with very little piping. This also has an advantage, in so much as all water troughs are within easy reach of the home, saving much time and worry. Do not forget to include a suitable spot for the orchard and garden. Erect stables and sheds on rising ground and on the east side of the home. The bore should be between stables and house. Plant a row or two of ornamental trees between the stables and the house, and a row of trees and a hedge on the western side of the house to act as a breakwind. The first year a 50-acre paddock should be fenced to provide a plot of early green feed. It is also advisable to grub a patch so that hay can be cut; this is one of the big problems that faces the new settler. The first year roll down as much scrub as possible and put in a big acreage, and leave some to be left under fallow. On new land one can command a bigger acreage than on old land. On new land it is possible to commence drilling in April, and perhaps sown dry, with no fear of weeds. To ensure a fair crop, not less than 70lbs. of super

to the acre should be sown; but with the seed sown early, on new land one may cut it down to perhaps 40lbs. with good results. Fences are an important item on a new block, especially where all timber has to be procured from elsewhere, but one should endeavor to erect a good boundary fence as soon as possible. For division fences, a temporary job will do until a decision is reached as to the subdivision of the block. For rolling scrub, I prefer a heavy roller, because there will then be less snags to deal with. With good fire breaks, burning should be done with a good hot north wind. All springbacks should be cut before burning, this being easier work than cutting and carting them off after the fire. It should be the aim of every man dealing with new land to do everything possible to ensure a good crop. This means a good stubble burn, and this means as much to him as the grain. Three good burns should be sufficient to kill most of the shoots, which is the aim of the man converting a virgin block into a farm." (Secretary, Mr. L. Orloff.)

NETHERTON.

October 8th.—Present: 24 members.

SHEEP IN THE MALLEE.—The following paper was contributed by Mr. A. McLean:—"The statements in this paper are intended to apply to sheep management only as regards the mallee lands east of the Murray. Every farmer should have a few sheep as soon as he can possibly get them; they are a most valuable asset on the farm. Fat lamb raising in this district is out of the question. At present the district is not suitable for the production of fat lambs; we are also too far away from market and freights are too high. Crossbreds of any breed are more difficult to handle than the Merino; they are also more inclined to roam into neighbours' paddocks, especially if he has better feed. Merino wool is the most valuable, and we grow in Australia the best Merino wool in the world, and always commands a good price. The farmer in the mallee districts does not, as a rule, possess good fences, therefore, the Merino being quiet, troubles the fences least of all breeds. The average farmer should secure, in the first place, a number of as good ewes as possible. Cast-for-age ewes from a stud is a very good plan; not more than his farm can carry easily, for overstocking is a very bad practice. Then through a reliable stock firm secure sires, or if he attends a stud sheep sale, ask a friend well up in the knowledge of sheep to select a sire suitable to your requirements, remembering always that our climatic conditions, coupled with the sandy nature of our soil, always creates a tendency towards fineness of wool. It is necessary to secure a robust, strong-woolled sire, then by careful culling, try if possible to have all one class of sheep, so that at shearing time there will not be two or three different classes of wool. The weighty fleece of about 64's quality is the most profitable wool to grow. Early lambs are best, but do not have lambs dropped before there is a reasonable chance of there being some green feed for the mothers. Ewes need careful attention during lambing; also have all lambs dropped within two months if possible. Almost every farmer can tail his own lambs, and the best time to do this is when the lamb is two to three weeks old. You can hardly tail a lamb too young, and it is safe to tail when they are four or five days old."

HARVESTER V. STRIPPER.—Mr. B. Temby read the following paper at the meeting held on November 19th:—"With a harvester one man can reap and clean the wheat in one operation, as against two operations, viz., reap and clean with a winnower. The man with a harvester can then cart his wheat to the market or barn, whereas his neighbor with a stripper has to feed his horses on hay until he cleans the wheat. It also allows the man with a harvester to get his paddocks cleaned out sooner and make use of the feed instead of feeding on hay. On an average crop with much cool weather the extra hay fed to a stripper team would be worth much more than the cocky chaff saved. Another point in favor of the harvester is that one can reap earlier and later than with a stripper, unless perhaps the plant includes a good power winnower, which will then make the stripper outfit much more expensive. Another saving is not having to travel the harvester to a wheat floor, and there is always an element of risk in the wheat heaps becoming damaged by rain. The harvester makes a better sample of wheat, producing less cracked grain, than with a stripper. It also blows out smut and wild oats better than wheat cleaned with a winnower after being reaped with a stripper. An 8ft. harvester costs £200, as against £170 for an 8ft. stripper, plus cost of winnower or the cost of winnowing each year, which would bring the cost of plant at least as high if not higher than a harvester. On 400 acres averaging 12bush. the saving in favor of a harvester would be about £50. The harvester would probably save a fortnight's time in harvesting operations, in which time all the wheat could be carted to market, leaving the man with a stripper his wheat still to cart. The harvester certainly saves no cocky chaff, but when the saving in wages, costs, and feed are gone into, it will be found that the saving of cocky chaff is an expensive item, especially as it is practically useless on its own. The country in this district—especially new land—is probably considered too

rough for a harvester, but I experienced no trouble last season with my machine except that the elevator box was sometimes bent through hitting big stumps. It made a good sample and worked satisfactory. The main items needing attention are to be sure and keep plenty of oil and grease on working parts, belts just tight enough so they will not slip, and keep all nuts and bolts tight." Mr. C. Wilkin also read a paper. (Secretary, Mr. C. Wilkin, Yumali.)

RAMCO.

October 14th.—Present: Eight members.

BUDDING.—Mr. C. Boehm read the following paper:—"Every gardener or fruitgrower should have a knowledge of budding, for often an undesirable tree or plant is discovered, and the best way to treat these is to bud them. If budding is not understood, very often these trees or plants are left for years, which means quite a big loss to the owner, and to engage a man for the job, if there are only one or two trees, may be rather expensive. It is always advisable to bud trees while still young. To bud older trees it is necessary to cut part or all of the tree right back to about 6in. stubs at pruning time. These stubs produce a mass of young growth. In the spring or early summer—when this growth is about 1ft. long—it should be thinned out and only those left required for budding in the best positions. Usually, about three or four will be ready for budding in December, preferably just after an irrigation to ensure a full flow of sap. Bud only after a cool change has taken place and so avoid disappointment. For the budding of deciduous trees, select buds from strong water shoots grown on the parent tree, but be sure that they are wood buds and not flower buds. Have a sharp knife, and cut the leaf from the selected bud to a short stub, then cut the bud, starting $\frac{1}{2}$ in. below and finishing $\frac{1}{2}$ in. above, and remove a small chip of wood from inside. Then insert in the "T" slit as quickly as possible and push bud down with the aid of the leaf stub as far as possible. Quickly tie the bud with raffia or bag twine on top first and then down as far as the slit, then wax it all over with grafting wax to exclude all air, and finally wrap some rag around to keep off the direct rays of the sun. In 10 to 14 days it is necessary to loosen all ties, when it will readily be seen if the buds have taken. If so, retie loosely, but there is no need to use wax this time, but the rags must be replaced. This will do for two to three weeks, when all ties can be removed, but if the weather is hot, retie the rags until a cool change takes place, when the rags can be removed. At the next pruning cut back just above the bud. These buds generally grow very rank the following spring, and are often damaged by strong winds in early summer. They require watching, and when about 1ft. long should be cut back to a bud facing the direction best suited for shaping the tree or to a lateral pointing the desired way. Repeat the shaping as the growth increases. By this method a tree can be better and more quickly shaped than if all the growth is left until the following winter pruning. Citrus trees are budded the same as deciduous trees, only the time of budding differs. For best results I find September and October and again in March and April the best time for inserting citrus buds. The buds should be selected from well rounded wood from near the base of some well grown extended shoot. It is not necessary to take out the little chip of wood from the citrus buds. A good grafting wax can easily and quickly be made at home by taking equal parts of tallow or any fat (unsalted) and beeswax and one quarter part of resin. Melt all together, and when cool will be ready for use." Discussing the paper Mr. Lewis said some years ago a number of trees shot below the bud and were as thick as one's arm before he budded again. He cut back to the main arms, and after they shot he budded, and now they were good trees. He asked whether it was advisable to cut the shoot above the bud, or allow it to go for a time. Mr. C. Boehm said not to cut the shoot. When the bud was growing cut a strip above the bud—cincture, about 2in. above the bud—and tie the new shoot to it. Mr. J. Boehm asked if it was possible to get success by budding into the older wood on citrus. Mr. C. Boehm said "No"; the bark was too hard. A bud from well-rounded wood near the base was necessary. If one had a large orange tree, bud two or three limbs and let the rest grow. In citrus budding particularly he advised putting wax around. Keeping air away was one of the main points.

A further meeting was held on November 3rd, there being present Mr. J. Boehm (Chair), and eight members. A paper, "Cincturing," was read by Mr. R. Bell. (Secretary, Mr. J. Odgers).

REMARK (Average annual rainfall, 10.52in.).

Mr. O. Weste presided at the meeting held on October 15th, which was attended by 18 members and 23 visitors. Mr. G. Quinn (Chief Horticultural Instructor) delivered an address, "The Codlin Moth." Mr. Quinn presented to Mr. M. Pethie the trophy for the Vine Section of the River Murray Pruning Competitions. (Secretary, Mr. W. Meier.)

TAPLAN.—Meeting held October 29th. Present: Seven members. Reports of the Forty-first Annual Congress were received and discussed. (Secretary, Mr. P. Hodge, Nangari.)

SOUTH AND HILLS DISTRICT.

BLACKHEATH.

October 9th.—Present: 11 members.

Mr. Pym read an article, "Pasture Management," from the *Journal of Agriculture*.

Meeting held November 5th. Present: 10 members. Numerous questions relating to stock troubles were discussed, and a paper, "Dairy Farming," was read by Mr. H. Paech.

Eight members were present at the meeting held on December 11th. Members discussed matters relating to the Wool Publicity Campaign.

At the meeting held on January 8th, Mr. H. Paech presided over an attendance of 10 members and visitors. A paper from the *Journal of Agriculture*, "The Control of Drift Sand," was read by Mr. R. Talbot.

Meeting held February 5th. Present: eight members and two visitors. The subject, "General Management of Draught Horses," was discussed. (Secretary, Mr. E. Paech, Rockleigh.)

BLACKWOOD (Average annual rainfall, 27in. to 29in.).

Meeting held October 13th. Present: nine members. Mr. W. Goldsack contributed an instructive paper, "American Orchard Practices."

On November 8th eight members of the Branch visited the Crayburn Estate.

A further meeting held on November 10th was attended by 14 members. Mr. B. Fowler (Manager Blackwood Orchard) gave an address, "Codlin Moth Control." (Secretary, Mr. R. Quinn.)

CHERRY GARDENS (Average annual rainfall, 35.03in.).

October 4th.—Present: 14 members.

Members visited the poultry yards of Messrs. Wright and Coles, of Longwood.

On November 1st 11 members and four visitors made a tour of inspection of the district in company with the members of the Mount Compass Branch and Messrs. W. J. Spafford and H. C. Pritchard (Department of Agriculture). Under the guidance of Mr. P. Wise (Secretary of the Mount Barker Branch) the visitors were afforded the opportunity of inspecting the bacon factory of Messrs. W. Jacobs & Sons and the experimental grass plots being conducted by the Waite Research Institute. Other properties visited included Messrs. Bates (dairy farm), L. Cowan and W. McDonald (stud sheep).

The annual social held on November 29th was attended by 16 members and visitors to the number of over 100, including delegates from the Blackwood, Kangarilla, Longwood, McLaren Flat, Scott's Bottom, Clarendon, and Balhannah Branches. Mr. H. N. Wicks (Vice-chairman Advisory Board of Agriculture) addressed the meeting, and musical and elocutionary items were rendered.

The meeting of January 3rd was held at the residence of Mr. M. Basey, and was attended by 11 members. The experiments in manuring fruit trees aroused keen interest. Afternoon tea was provided by Mrs. Basey. (Secretary, Mr. A. Stone.)

GUMERACHA (Average annual rainfall, 33.45in.).

October 10th.—Present: 10 members and two visitors.

An instructive address, "Sheep Breeding," was delivered by Mr. W. Hanna.

On January 5th Mr. W. J. Spafford (Deputy Director of Agriculture) addressed members on the subject "Fertilisers and Manures." There were present 15 members and visitors.

The meeting of February 2nd was held at Mr. A. Cornish's residence, there being present 14 members. Mr. W. Boerth read a paper, "Systematic Farming." (Secretary, Mr. L. Wise.)

HARTLEY (Average annual rainfall, 15in. to 16in.).

September 10th.—Present: 16 members.

"BENEFITS TO BE DERIVED FROM THE AGRICULTURAL BUREAU." The following paper was contributed by Mr. W. Lawton:—"The Agricultural Bureau is largely responsible for the adoption of many up-to-date and scientific methods of farming. Those who become members of a branch should join with the intention of doing something to improve the branch. If members attend meetings regularly and take a live interest in the work they will probably find that some of the other members have mastered problems that they have been trying to overcome. Punctuality and regular attendance should be strictly observed by all members. During busy seasons it is often impossible for members to attend meetings, but during the other portions of the year members should be able to devote one night a month to the Bureau. Not only the individual,

but the district is benefited by the Agricultural Bureau. Each branch, to be a success, should be a live organisation. The Secretary of the branch can do much towards the success of the branch, but he cannot do everything, and it is the duty of members to assist him in every possible way. The younger men especially should be impressed with the advice and help that can be obtained from an active membership. By attending the meetings, they are given an opportunity of hearing the views and experiences of older members, which often enables them to avoid such mistakes as might have been made in the past. To the younger men the Bureau also stands as an education for public speaking. The knowledge of the officers of the Agricultural Department is always at the disposal of members. Any question put to those officers is most willingly answered. The reading of a paper at a meeting may appear a small item, but the discussion that takes place will be of some interest and benefit to all present. The fact that branches are to be found in all progressive districts is sufficient proof of the high esteem in which the Bureau is held by the man on the land."

Twelve members were present at the meeting held on October 9th which took the form of a "Question Box." (Secretary, Mr. D. Harvey, Hartley.)

INMAN VALLEY (Average annual rainfall, 27in.).

October 16th.—Present: Nine members and three visitors.

Mr. R. Gregory gave a report of the proceedings of the Annual Congress.

TOUR OF THE DISTRICT.—On November 13th, 11 members and four visitors made a tour of inspection of several holdings in the district. The first property visited was that of Mr. Nosworthy, who conducted the party over a paddock that he had successfully cleared of scrub. Before clearing, the land would only carry a few sheep; it is now carrying several sheep per acre. The paddocks were sown with Subterranean clover, top dressed, and are now showing a rich growth of clover and natural grasses. Where the scrub was burned off last season it shows a distinct line between top dressed and undressed pasture. Questioned regarding shoots, Mr. Nosworthy stated he had had no difficulty with them, the few left after burning were eaten by the sheep, and the shoots gradually died as a result of the constant eating back. A few might need knocking off: these should never be left until the second year, because they were then harder to kill. Mr. Nosworthy stated that the ti-tree was so dense that he had great difficulty in getting the super spreader through, and now there were only a few bushes left. Next inspected was a paddock of light sandy soil which was once covered with black grass on Mr. Dennis' property. This was ploughed, sown with clover, and top dressed. This pasture has made remarkable first year growth. In some places the super did not quite reach the last round, and the few clover seeds that are trying to grow without the aid of super are very stunted. The party next visited Mr. Stone, who showed a paddock that had been cleared and burnt off. On this he broadcast Perennial rye and Subterranean clover with super, following up with the harrows instead of ploughing. It was noticeable how well the rye grass was growing in any thick deposits of ashes, such places as where logs had been burnt. It would probably pay to scatter rye seed wherever any logs had been burnt. Mr. Kay showed the party over a paddock, on which he had sown clover with oats as a cover crop. This was also scrub land cleared and ploughed. As a first season's growth it was very good, and should be very valuable later on for fattening sheep. (Secretary, Mr. H. Lewis.)

LONGWOOD (Average annual rainfall, 37in. to 38in.).

October 4th.—Present: 10 members and 17 visitors.

QUALIFICATIONS OF THE POULTRY FARMER.—Meeting held at the residence of Mr. J. R. Coles. Members and visitors, including 14 members of the Cherry Gardens Branch, inspected the poultry farm, incubators, brooders, etc. Mr. H. Wright read the following paper:—"It will be noted by those who have had the opportunity of inspecting a number of poultry farms that a progressive man does not confine himself to a rigid set of ideas, but is ever ready to consider and adopt proposals likely to increase his production, or enable him to carry more stock. In the time at his disposal he should endeavor to keep in stride with the progress of time. There is an old saying: Have a cage in which to put your bird before you catch it; and this holds good in poultry farming. The housing then is the first consideration, and one should learn and know a great deal about housing. In times of high wages and high prices for material he should have the ability to erect buildings in the most convenient and economic manner. In a district with a heavy rainfall he will find it advisable to put in good concrete floors, and he will need to pay attention to light and ventilation. He must continually study stock selection. His motto should be: Keep pegging away towards improving the flock, almost daily culling birds as they become backward in production. He will find that scientific breeding is a subject for constant study. Incubator handling requires very close attention and varied treatment during hatching, according to circumstances of climate. Chicken rearing, although very interesting, is at times trying, and keeps one close to his job. Feed wisely, so that the birds are always progressing and healthy.

Best and cleanest foods will work towards this aim and keep down mortality. As his table selections are fattening he must begin early, looking up prospective buyers. It does not pay to keep table birds over time. Birds for table are differently fed to those set aside for egg production. Poultry farming embraces a wide scope in agriculture, and undoubtedly it is an interesting phase of rural activity."

GRASSES.—A paper on this subject was read by Mr. W. Hughes at the meeting held on November 1st, 1930:—"On our small holdings we can produce a great many household requisites, thus cutting out cartage, commission, etc., on those lines. Most landholders in this district can grow all the fruit for dessert cooking, jams, and vegetables for home use if we have sufficient manures, and if we keep a cow or two, some pigs, and poultry they make us fairly independent. But it is not wise to put our hand into our pocket too far for manures or feed for our stock, otherwise we could buy produce instead, and at less cost. Whatever stock we keep, be it a horse, cow, pigs, or poultry, means useful manures, and grass is a big help in feeding such stock. In established paddocks stock can utilise grass from about August to the end of December, and if sufficient is available some can be cut for hay. Barley grass appears after the autumn rains, and on good soil can be cut three or four times until the seed prickles become a nuisance. Prairie grass gives feed almost as soon, and gives a better cut, but not so many, and if grazed stock will eat it out. Rye grasses, rib grass, cocksfoot, and fog each have their advantages and disadvantages. I grow them mixed together. Couch grass is not much good as a feed, spreads rapidly, and is hard to get rid of. Clovers should be represented in the mixture. They grow in undrained swamps where most grasses would perish in winter, and most of them are perennial—last for several years without re-planting. Subterranean is a splendid paddock clover on either hills or swamps. It is good feed from early August to Christmas in average seasons, and, cut in November, makes good hay. It is something of a trouble to cut and cure, and fed green it scours the cows. Give stock dry hay at the same time to check this. Perennial red clover (cow grass) makes a better hay, is more easily cut and cured, and when fed green does not scour so much; but is not so hardy. Under irrigation it will give three good cuts during summer and a lot of feed in each cut. Alsike clover is much like it in growth. Two cuts (under irrigation) can be made, but these are heavier ones than those from cow grass. Cattle eat readily both of these grasses, either green or as hay. Italian crimson is a hardy annual, gives a good body of feed on high land, but cows prefer any of the other clovers to it. For other periods of the year lucerne will give six to seven cuts during summer—not nearly as heavy as clover cuts—under irrigation, but only three cuts without irrigation. Millets, Sudan grass, maize, &c., planted on our high lands in October help us until frosts come, and by planting oats or barley and rye mixed in April we can cut them from July on or have them until November for hay. With annual crops there is always the expense of ploughing, seed, manure, &c., and risk of failure, whereas the established grass paddock is there for several years. Considering the last year's price of fruits and vegetables, what they cost to produce in labor and manures and to market, and that there seems no reason to expect better this season, I recommend grass paddocks because they are no outlay when once established. The stock manure them. Sheep mean wool and lambs and mutton for the table. Cows mean milk, cream, and butter for the table, and skimmed milk for calves and pigs; both of which help the table and cost very little if plenty of milk and grass is used. Poultry mean eggs and chickens, and a grass paddock helps feed all of these."

A meeting was held on January 31st at Mr. L. Davey's residence. Members report a light apple season. Mr. Davey's cultivation of vegetables under irrigation aroused keen interest. Mr. W. Hughes related his experiences in marketing pigs. (Secretary, Mr. J. E. Coles.)

MOUNT COMPASS.

October 2nd.

Mr. A. Kidman presided over an attendance of 38 members. Several McLaren Flat members also were present. Mr. R. Troit, of the McLaren Flat Branch, gave a lecture on "Motor Cars," in which he gave a resume of motor statistics and traced the development of the industry. Mr. Ingerson, who was Chief Engineer of the British Phosphate Commission in Nauru for 15 years, gave an address, "The Origin of Phosphate and Island Conditions." Delegates reported on the Annual Congress. (Secretary, Mr. J. Black.)

ROCKWOOD.

October 13th.—Present: 11 members and seven visitors.

DAIRYING.—In the course of an address on this subject, Mr. J. Hudd, of the Hartley Branch, said all breeds were good, but advised when once a breed had been selected, to stick to it and try to have a uniform herd. All the cows needed to be well fed and looked after if good returns were expected. A cow could only make milk from the material given her. He gave reports of tested heifers to show the results of careful

breeding on right lines. He advised every man to buy the best breeding stock he could afford, and each time he bought to try and go for something better. In this way he would gradually lift the standard of his stock. He believed in letting the stock have all the salt and other licks they could use. His method was to grow all his own feed, crushing all corn, and he gave the cows 12lbs. chaff and 5lbs. corn as a daily ration.

CONSERVATION OF FODDER AND SEED WHEAT.—Mr. M. Myer read a paper on this subject at the meeting held on November 10th:—"After the lean period experienced during the past three years, farmers might be tempted to dispose of the whole of their produce to secure as much ready cash as possible. They would be well advised, however, to overlook the economic side of the question. For instance, it would be very bad business to sell wheat at milling prices, and then have to turn round and buy seed requirements at from 1s. to 2s. increase on that price. Apart from these aspects, it might not be possible, owing to the very difficult financial position, for the Government to extend the same measure of assistance as it has granted in the past. Where dairying and pig feeding are carried out, the holding back of sufficient grain for feeding the cows is most essential. In spite of the low prices of bacon and butter fat, and the low level of grain prices, there should still be a payable margin left in favor of feeding to animals. The conservation of fodder for use during periods when pastures and crops are dormant, is a sound investment, and particularly so where dairying is carried on. Prior to harvest one should consider the amount of hay that will be required to carry over until the next harvest is available, and it is well to have a good reserve on hand, and in the event of perhaps having a long dry autumn, it may be found necessary to feed the breeding ewes or other stock." (Secretary, Mr. M. Meyer.)

STRATHALBYN (Average annual rainfall, 19.43in.).

Meeting held October 15th. Mr. F. Laycock, Manager of the local Branch of the National Bank, read an instructive paper, "Banking and Finance."

Mr. C. Goddard, of the School of Mines, gave an address, "Wool-classing for the Farmer" at the meeting held on November 18th.

A meeting was also held on November 5th. There was an excellent attendance of members and visitors, including a number of ladies. Dr. C. Wing delivered an address, "Hygiene and the Public Health." (Secretary, Mr. F. Allison.)

TWEEDVALE (Average annual rainfall, 35.96in.).

October 9th.—Present: 26 members and three visitors.

QUESTION BOX.—The following subjects were discussed:—What is the best breed of fowl for this district? *Answer.*—One member stated that the White Leghorn was the best breed in egg production. The Brown Leghorn was not so consistent in egg production. For dual purposes the Black Orpington or Black Minorca were favored. Success in any district was wrapped up in proper housing in cold weather. When is the best time to plant lawn grasses? *Answer.*—September or October. Cuttings should be planted in rows 6in. apart. What is the best feed for young turkeys? *Answer.*—Chopped onions mixed with pollard, also hard boiled eggs, cracked grain, and shell grit. For the first five or six weeks young turkeys should not be allowed to run out in the mornings, because of the danger of the young birds getting wet from running through grass.

APPLE CULTURE.—Mr. R. Hunter, M.P., in the course of an address on this subject at the November 6th meeting, said the best soil for a fruit garden was a hard, firm, heavy soil with ironstone in it. Such soil would produce a good show apple with plenty of color. It was not necessary to cultivate deeply. Selection of trees was of great importance, as a tree which was stunted in its early life would never develop into a vigorous fruit-producing tree. He was in favor of keeping the tree low, as this gave them more vigor and facilitated picking. Fallowing was necessary to give the air a chance to get into the ground. A crop could be successfully grown in an off season if the tree was stripped in a crop year. By not allowing the tree to bear it would retain its vigor, and would produce a crop the following year. A good plan was to strip half the orchard, one would then have a fair crop each year. He did not favor burning the blossoms off with a strong spray during the flowering period. Cultivating and manuring were necessary. In the year that the tree was stripped pruning should not be carried out, but the following year, when the tree was required to produce a crop, it should be pruned. He maintained that through careful pruning one could get more fruit. *Spraying.*—The early January spray for codlin moth was the most important. (Secretary, Mr. B. Schapel.)

UBAIDLA AND SUMMERTOWN (Average annual rainfall, 44.25in.).

Meeting held October 6th. Present: 12 members and several visitors. Mr. A. Cobbledick delivered an address dealing with his trip to Tasmania to attend the fruitgrowers' conference. (Secretary, Mr. G. Prentice.)

CROWN LANDS.

LANDS TO BE OFFERED SHORTLY.

Lands in the Hundreds of BENARA, COMAUM, GAMBIER, JESSIE, JOANNA, KONGORONG, LAKE GEORGE, MAYURRA, McDONNELL, MOUNT BENSON, NARACORTE, RIVOLI BAY, STIRLING, SYMON, and WATERHOUSE.

When offered full particulars will be published in the *Government Gazette*, and plans and detail may be obtained on application to the Director of Lands, Adelaide.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences of Branches of the Agricultural Bureau are being arranged as follows:—

River Murray, at Renmark, June 18th (Mr. W. E. Meier, Secretary.)

Far West Coast, at Ceduna, July 1st (Mr. E. H. Fear, Secretary.)

Upper North, at Willowie, July 15th (Mr. H. A. Crisp, Secretary.)

The above Conferences will commence at 10.30 a.m. in each case. Papers and questions for Conferences should be sent to the General Secretary, Agricultural Bureau, about a fortnight prior to the respective dates mentioned.

Pruning Competitions.

Pruning competitions in various parts of the State will be held as under:—

River Murray Branches of the Bureau (Mr. J. J. Odgers, Ramco, Secretary).—Mypolonga (date to be fixed); Cadell, June 10th; Waikerie, June 11th; Moorook, June 12th; Berri, June 15th; Renmark, June 16th; championships, at Berri, on June 17th.

Lower North Branches (Mr. J. S. Hammat, Williamstown, Secretary).—Watervale and Penwortham, June 9th; Lyndoch, June 12th; Angaston, June 22nd; Light's Pass, June 24th; Lone Pine, June 29th; Williamstown, July 1st. The championships will be conducted under the auspices of the Lone Pine Branch, and will be held near Tanunda on July 1.

Springton Branch (Mr. E. Brokate, Secretary), June 12th.

The Reynella Competitions will be held on Friday, June 26th.

The Future for Wheat.

Speaking during the discussion which followed the reading of a paper, "Profitable Farming on a Small Holding," by Mr. B. P. Dutschke (Kilkerran), at the Yorke Peninsula Conference, at Maitland, on April 15th, Professor Perkins said it was not for farmers in districts such as those on Yorke Peninsula, where high yields of grain were received, to think of withdrawing from the growing of wheat. No man could be a good farmer who was not an optimist. "If you want to be a pessimist go and live with those in the city! How are you going to live, then, and how are you going to occupy your time?" No man on the land could afford to give up an occupation which it had taken years to master. They hoped that where it was necessary State assistance would be available. Every man on the land was under certain responsibilities. The farmer produced something without which the State could not do, and, recognising their responsibilities, men on the land were not likely to throw up the sponge. He realised that they were receiving prices for their grain which were not economical. But farming was essentially a means of earning a living and profits were always problematic. They could do very well without the luxuries of city life, and indeed were much better off without them. There was not the slightest doubt that prices would rise in the near future, and everyone hoped that it would be by next harvest, and personally he believed that would be so. Present prices were absolutely without equal in the history of the State. Since South Australia had been growing wheat there had been no year when prices had fallen lower than 2s. 3d., and that was in 1893, and in the current year wheat had not averaged over the State more than 2s. Further, with exchange rates at a normal figure, that would be about 1s. 6d. The present low price could not be expected to continue indefinitely. Land would go out of wheat in other countries which could put the land to other and more profitable uses. From 1924 and onwards rye was used extensively in Europe because wheat was too high in price for breadmaking, but with current low prices for wheat, which were actually lower than those of rye, it was only natural that the consumption of wheat should gradually be

restored to normal. There would probably be a reduction in the area sown to wheat, a greater consumption, and the large surplus which had accumulated would gradually disappear. His view regarding the low price for wheat was that this could be largely attributed to the action of the North American Wheat Pools in their vain endeavor to check the normal fall in prices of the post-war boom. He had no personal feelings in this matter. The pools, instead of allowing the price for wheat to take a normal course, held it back and so accumulated huge surplus stocks of grain. These, of course, could not be held indefinitely, and when this point was realised, stocks were released, which resulted in an abnormal fall in prices. But for this he believed that prices to-day would be in the vicinity of 3s. 6d. per bushel. If people tried to handle an article of produce like wheat, which was grown practically all over the world, and endeavored to interfere with its normal circulation, there was the danger that they would do considerable harm to those concerned in its production.

Concluding his remarks, Professor Perkins said, "I hope that you farmers on the Peninsula will try to put in as much wheat as you possibly can. You will have no cause to regret it, and I feel certain that all the assistance that the State can give will be given."

Side Lines on the Farm.

"The main object of side lines on the farm is to support the results of main crops," said Professor A. J. Perkins (Director of Agriculture), in reply to the question, "What is the most profitable side line on the farm at present and what breed would be suggested?" which was submitted by the Kilkerran Branch at the Conference of Yorke Peninsula Branches at Maitland on February 15th. Continuing, the Director said it was unfortunate that in a comparatively short period of time farmers in South Australia appeared to have forgotten the value of side lines, and they had now found that in normal circumstances the farm could not reasonably stand on its own with one type of crop. In the past, when they talked about costs of production, practically the whole of the discussion centred on wheat, but it would be fairer to look as well at the profits earned by the whole of the farm. Looking at the question from a personal point of view, the Director thought that all the various side lines should be availed of to some extent, but in order of preference he would place dairying on a limited scale first. Cows presented the advantage of bringing in a sum of ready money every two weeks. It was not easy to secure good cows, and in that direction they largely had themselves to blame. During the past five years the State had lost 30 per cent. of its dairy cows, because South Australians had considered dairying irksome. In the second place, he recommended poultry, because here again was a source of ready money; and, thirdly, the farmer should consider the raising of fat lambs or the maintenance of a farm flock. In the case of sheep, the revenue was not so regular, and although they might have to pay high prices for cows, sheep could not be handled on an average farm without additional expenditure. Fences, proper subdivision of the farm, and the provision of adequate water supplies were necessary to the successful management of the flock. For the average farm, they could not get away from the well-developed, large-framed Merino ewe, although he recognised that the crossbred ewe would produce a better lamb; but the difficulty was to secure suitable crossbred ewes, and it was a mistake to expect the average farmer to raise his own crossbred ewes. That meant keeping two types of rams, which would frequently lead to a good deal of confusion. The farmer would have to rely on the Merino ewes which could be purchased off shears. With the rams, there was a certain amount of difficulty, and they must consider this question from a national point of view. The type of export lamb was definitely for a well-developed, early maturing lamb, acceptable on the British market, and for this one of the Down types of ram, the dark-faced rams of the British breeds, was essential. Of these the best was the Southdown. Lambs from this cross were not very large at birth, and lambing difficulties would not be serious. Much also could

be said in favor of Dorset Horn. There was not a better type of lamb than the latter for the local market. Crossed with the Merino, it produced a lamb which grew very rapidly and matured early. There was, however, the danger of trouble at lambing time with this cross, because of the shoulder development of the breed. He hoped that farmers would see the desirability of conducting side lines on the farm, in order to make the growing of wheat a less precarious occupation than it was at the present time.

The World's Barley Crop.

In a recent statement regarding the world's barley crop, the Ministry of Agriculture (England) reported that the crop of 1930-31, although somewhat smaller in total to that of 1929-30, had again been well over the average, the latest estimates indicating a total production (apart from Russia) of 618 million cwts. against 643 million cwts. in 1929-30, and the five-year average of 534 million cwts. In the United States and Canada the combined crop of 199 million cwts. exceeded that of the previous year by 25 million cwts. The European crop, however, at 321 million cwts. showed a reduction on the year of 9 per cent., although for the most part harvests were above the average, while in North Africa and Argentina yields were generally below average. Although the European crop in total was distinctly smaller than in the preceding season, harvest results in the exporting countries in the south-east were generally good. In consequence the export movement from that area had been maintained at last season's level, while in addition there had been a material increase from Russia. Shipments from other sources, however, had generally declined. Imports into the United Kingdom at 12 million cwts. in the seven months ended February, 1931, had been about 3½ million cwts. larger than in the corresponding period of last season, but the increase did not entirely compensate for the reduction of 5 million cwts. in the home crop. During the current season the largest individual source of supply had been Russia with 4,800,000cwts. against about 400,000cwts. only in the seven months ended February, 1930. Roumania had supplied 2,100,000cwts., an increase of 600,000cwts., but imports from the United States and Canada had together fallen by over 1 million cwts. to 2½ million cwts.

Essays in Agricultural Economy.

In order to commemorate the marriage of Prince Humbert of Italy and Princess Marie Jose of Belgium, the International Institute of Agriculture, Rome, has instituted the "Humbert-Marie Jose" annual prize for the best work on agricultural economy. The prize will consist of a gold medal and the sum of 10,000 lira (£108 in London, par), and entries must be submitted before September 30th. Only the works of authors who are nationals of countries adhering to the Institute and which have been published in the course of the two preceding years shall be eligible for competition. A set of regulations governing the competition and the manner in which works on the subject should be forwarded may be seen at the office of the Minister of Agriculture, Adelaide.

Handling of Citrus Fruit for Export. A Correction.

In commenting on the recommendations of the Citrus Preservation Committee of the Council for Scientific and Industrial Research, published on page 906 of our April issue, Mr. Geo. Quinn (Chief Horticultural Instructor) has pointed out that the dimensions of the export citrus case were wrongly given by the Committee. The report stated, "Only export citrus cases (23 x 11½ x 11½ inside measurements clear of a division) should be used," &c. This should have been "Only export citrus cases (24 x 11½ x 11½ inside measurement) should be used," &c. The Chairman of the Committee has also written asking us to draw attention to the error in the report.

Shearing Three Times in Two Years.

Is it payable to shear sheep every nine months and three times in two years? (Taragoro Agricultural Bureau). Mr. A. H. Codrington (Wool Instructor, School of Mines) supplied the following reply:—

"Should the wool of 12 months' growth be typed, suitable for the English system of combing, it almost invariably follows that wool of nine months, owing to its

Scientific Farming!

THAT is the only proper response to present troubles—**THAT** is the road to solvency and restored prosperity. . .

Economies are necessary, but to cut the application of super in this years farming effort would be a fatal mistake. .

Science and Economy dictate the liberal use of

W.M.L. EXTRA HIGH-GRADE SUPER

for it lowers costs by increasing yields.

shortness of length, would be appreciably affected in type and spinning quality, resulting in the clean scoured value being lowered to correspond with the changed degree of type; hence, the price for nine months' wool would probably be from 1d. to 1½d. per lb. less than that paid for 12 months' growth. It is possible, however, that three shearings in two years would yield a slight increase in the total weight of wool per sheep, but against this advantage must be debited the cost of third shearing.

"Assuming, then, that there is no difference in price of wools per pound, sheep would have to yield at least 12½ per cent. more wool per head over two years at present prices, to show the slightest advantage, after allowing for the cost of the extra shearing. In this explanation, any possible natural advantage or disadvantage that might be associated with such a venture has not been taken into account."

AGRICULTURAL INQUIRIES.

[Replies supplied by PROF. A. J. PERKINS, Director of Agriculture.]

Barley on Stubble Land.

"Which is of greater advantage for the production of barley, to work stubble land wet or dry and with the cultivator or plough?" Maitland Conference. There are two points to this question. So far as the moisture content of the soil is concerned barley is not greatly affected. Much depends on the type of soil on which the crop is to be produced, either grass land or stubble. Grass land will not be so satisfactory as stubble land, because barley should not be grown on land too high in fertility. On stubble land on Yorke Peninsula the Director thought it would be immaterial whether the soil was broken up either wet or dry, provided they could work it down late in the season. If the land was of a heavy nature, it would be necessary to wait until sufficient rain was received to enable the implements to deal with it. On light land, the cultivator would be all that was necessary for barley sown on stubble produced on good fallow of the previous year. The plough would be needed to deal with heavy land.

Barley Growing on Stubble Land Without Super.

"Can a profitable crop of barley be expected on wheat stubble without super?" Maitland Conference. The reply to this question depends whether it refers to land that has been treated for a number of years or not. Most of the land on Yorke Peninsula has been dressed very consistently with super for many years. If, for instance, they had land that had carried crops for 20 years and the crop had been treated with a 1cwt. application of 36 per cent. super, it would mean that the land had received 1 ton of super in that period. From that there would certainly be a big residual amount of phosphate left. In the case of those farmers in straitened circumstances, it would not be necessary to use super on old land. Barley did not need a very fertile soil. If, on the other hand, they had to deal with land that had not been cultivated for a number of years, it would be preferable to give a light dressing of super, say, 45lbs. to the acre.

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

100 Per Cent. Superphosphate.

"How does 100 per cent. super compare with lower grades when freighted 120 miles on the railways?" ("M. C. C.," Yurgo). Reply—All superphosphates, i.e., all water-soluble phosphates on our market contain the same fertilising constituent, namely, phosphorus combined up as mono-calcic phosphate, and so are strictly comparable as to price and effectiveness. One ton of 100 per cent. superphosphate contains the equivalent of 2,240lbs. tricalcic phosphate; 2.08 tons of 48 per cent. superphosphate contain the equivalent of 2,240lbs. tricalcic phosphate; 2.22 tons of 45 per cent. superphosphate contain the equivalent of 2,240lbs. tricalcic phosphate.

1 ton of 100 per cent. superphosphate, at £11 5s. = £11 5s.

2.08 tons of 48 per cent. super, at £5 = £10 8s.

2.22 tons of 45 per cent. super, at £5 15s. = £10 10s. 11d.

120 miles railway freight, 11s. 2d. per ton for superphosphate; tarpaulin, 2s. 8d. per truck.

| | 1 ton 100% superphosphate. £ | 2.08 tons 48% superphosphate. £ | 2.22 tons 45% superphosphate. £ |
|-------------------------------|------------------------------------|---------------------------------------|---------------------------------------|
| Cost of manure | 11 5 0 | 10 8 0 | 10 10 11 |
| Freight (120 miles) | 0 11 2 | 1 3 3 | 1 4 9 |
| Tarpaulin | 0 0 4 | 0 0 8 | 0 0 8 |
| Cost at siding | £11 16 6 | £11 11 11 | £11 16 4 |

These figures show that at railway sidings 120 miles from the place of manufacture, amounts of 100 per cent. and 45 per cent. superphosphate, containing the same quantity of phosphate of lime, cost almost exactly the same figure, whereas 48 per cent. superphosphate is cheaper. There is, however, much less material to handle where 100 per cent. superphosphate is being used; but, on the other hand, the distribution of the lower grade of superphosphate is always more regular than where smaller weights of higher grade are drilled in.

GRUBBING

POULTRY INQUIRIES.

[Replies supplied by Mr. C. F. ANDERSON, Government Poultry Expert.]

Profits from Poultry.

"What would be the approximate profit in a year from 200 White Leghorn hens at the present price of foodstuffs, calculating the price on the past year for infertile eggs?" (Maitland Conference). Reply—The approximate profit from 200 White Leghorn hens depends on a number of circumstances, the principal of which are—

1. The period of hatching.
2. The method of feeding.
3. Whether good laying strain stock or not is kept.

In dealing with the period of hatching, it is necessary for profitable egg production that a percentage of winter egg production should be obtained when egg prices are at their highest. In order to do this, I recommend for the Peninsula districts White Leghorns, hatched during August and September.

The method of feeding to be recommended is:—Morning: Wet mash, composed of 1 part bran, 2 parts pollard, 1lb. meat meal per 100 birds; in summer months 60 per cent. green feed, and 40 per cent. green feed in winter months. Crushed wheat can be substituted for the pollard. The average quantities to be fed per bird daily is bran $\frac{1}{2}$ oz., pollard or crushed wheat 1 oz. Wheat at midday and night at the rate of 2ozs. per bird per day.

The class of stock is also an important factor. Some classes of stock will produce only 7 dozen or 8 dozen eggs per year, while others will produce 15 dozen to 16 dozen per year. The size of the egg must also be considered. Some strains of poultry lay a large percentage of small eggs. The aim should be to select a strain that will average on the farm from 12 dozen to 13 dozen eggs per year of an average weight of 2ozs. per egg.

Assuming that the above essentials have been closely followed, a flock of 200 White Leghorn hens laying an average of $12\frac{1}{2}$ dozen eggs per year would produce 2,500 dozen eggs per year. Basing the average net return to the producer of guaranteed new-laid infertile eggs at 10d. per dozen, the return for the 2,500 dozen would be £104 3s. 4d.

Each bird would consume $1\frac{1}{2}$ bush. of wheat per year, and basing wheat at 2s. per bushel on the farm, the feeding cost would be 3s. Add another 1s. per bird for cost of greenfeed, meatmeal, shell grit, &c., making a total of 4s. per bird, or £40 per year for 200 birds. The value of eggs produced by the 200 hens would be £104 3s. 4d., less £40 as cost of feeding, leaving a net return of £64 3s. 4d. to the producer.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

"E. E. R.," Narridy, has mare with evil smelling discharge from left nostril. There is no evidence of the mare having a cold. Reply—The trouble is due to either a piece of decayed bone in the back of the nostrils, or to an infection of the sinuses of the head. The latter condition may arise as a sequel to a previously occurring cold, or be due to some teething trouble (such as a decayed tooth). The only treatment you can give is repeated inhalations of medicated steam. This may to some extent help to alleviate the condition, but a cure is only likely to result if you can have the animal surgically treated by a qualified veterinary surgeon.

Secretary, Agricultural Bureau, Weavers, reports—(1) Heifer calf gone practically blind. (2) Heifer with ulcers around top of teats. (3) Pigs very weak in legs. Replies—(1) During the last three years a number of similar reports have been received. The

cause is unknown, but thought to be due to the absence of certain substances (vitamins) in the food supplied. There is no treatment which as yet has proved effective, but you may try administering once a day with the milk two tablespoonfuls of cod liver oil. (2) Clip the hair from adjoining skin, and after each milking apply a little of the following mixture with a camel hair brush, first drying the teats:—Take tincture of iodine, Friars balsam, glycerine, equal parts. The condition is most probably caused by leaving the teats wet after milking. Concentrates should be fed at the rate of 3lbs. of concentrates mixed with chaff for every gallon of milk produced by the animal. (3) Apparently there is a lack of minerals in the feed mixture supplied, which latter is especially necessary in growing animals. In the milk give cod liver oil at the rate of a teaspoonful for each pig once daily and feed the grain crushed and dry. Mix with each 100lbs. of crushed grain 1lb. of ground rock phosphate. If you have a plot of lucerne a small bundle once a day should be given.

“A. S. T.,” *Bowhill*, reports—(1) *Horse with lumps on the shoulder and knee.* Replies—(1) *Lump on shoulder.*—This is due to the formation of what is termed a “cold abscess,” which is slow in development and not accompanied by symptoms of acute pain or much heat. The treatment indicated is to hasten the “pointing” of the abscess by application of hot water to the part twice a day and then opening at the lowest point with the point of a sharp penknife to allow evacuation of pus (matter) and to allow efficient drainage. Sometimes a blister is applied to the swelling with the same object of causing it to point, but heat in the form of hot fomentations is best. Owing to the thick wall which surrounds the abscess a complete cure can often only be obtained by a radical operation under chloroform, which would have to be carried out by a veterinary surgeon. (2) *Lump on knee.*—From description supplied, it would appear that a fracture of some of the bones has occurred at some time, and in healing the main joint of the knee (hinge joint) has become knit. The only treatment is the application of a blister to front of the knee and rest.

Secretary, Agricultural Bureau, Springton, reports a heifer with diarrhoea and swelling of cheeks. Reply—Swelling of the cheeks is indicative of debility which has

Sole Agents, Grenfell Street,
ADELAIDE.

in the first place been caused by the diarrhoea. Treatment—Commence by giving the animal the following drench:—Raw linseed oil, 1 pint. Twenty-four hours later give the following mixture:—Prepared chalk, 4ozs.; tincture opii, 5ozs.; tincture catechu, 5ozs.; spirits of chloroform, 5oz.; water, add 1 pint. Make mixture. Directions—Give 2 wineglassfuls three times a day in 1 pint of flour gruel. Keep the animal in a stall and feed on good quality chaff with a little pollard and crushed grain added. A sample of the animal's manure will be examined if forwarded.

"J. B.," *Ramoo*, asks for treatment to keep flies off cows and horses. Reply—There is no application for this purpose that can be applied to the animal's skin with any lasting effects, and it is therefore necessary to re-apply these frequently at intervals. The following applications are stated to be as effective as any:—(a) 1 part fresh Laurel oil, 10 parts linseed oil. (b) 1 part fresh Laurel oil, 4 parts diluted spirits, 5 parts olive oil.

"K. M.," *Mount Gambier*, asks what action mustard has when incorporated with drenches for sheep worms. Reply—The administration of mustard along with copper sulphate to sheep for internal parasites is recommended by the Department of Agriculture, New South Wales, on the grounds that the stimulant and carminative properties of the mustard offsets certain astringent and antiferment properties of the copper sulphate solution on the alimentary canal. Experimental evidence indicates that the mustard itself has little or no specific action as a vermifuge.

Secretary, Agricultural Bureau, Brentwood, reports death of ewes in good condition and carrying twin lambs, unable to stand for two days prior to death. No other symptoms in evidence. Reply—The mortality is due to a condition known as "Toxaemia of pregnancy" which only affects ewes in good condition and during the last five weeks of pregnancy. The malady is always associated with good condition and lack of exercise. No medicine has proved successful as a curative agent, though the administration of treacle or molasses (two tablespoonfuls in a cup of water) may be tried. The condition may be prevented by keeping pregnant ewes in just good store condition and making them exercise. This can be done readily by placing them in a paddock containing not too much grass, &c., so that they have to exercise to get a bellyful. If feed is plentiful in paddocks, put them on to the fallow or exercise them daily. Any hand feeding should be kept over until after they have dropped their lambs.

"J. M. C.," *Waikerie*, reports horse with swollen penis. Reply—Draw penis out from sheath and wash thoroughly with hot water and soap. Clean up sores. Dry area and apply carbolic vaseline over penis and sheath. Dress sores daily with the vaseline. If no improvement, syringe sheath out daily with a 2 per cent. solution of zinc sulphate.

"V. E. W.," *Millendilla*, has horse listless, dull, and falling away in condition. Reply—Try the following treatment:—Give this drench—Raw linseed oil, 1½ pints; spirits of aromatic ammonia, 1oz.; spirits of nitrous aether, 1oz. The following day commence giving Fowler's solution of arsenic twice a day for 14 days, the dose being 1 tablespoonful in a little chaff and bran, or direct into the mouth. The amount of solution required for the course of treatment is a 1lb. bottle. Report progress at the end of treatment.

Hon. Secretary, Agricultural Bureau, Rendelsham, reports—(1) Horse continually trying to pass water, and turns head around towards stomach. (2) Cow with "tucked up" appearance and hunched back, falling away in condition. Reply—(1) The horse has sub-acute colic, and the following treatment is suggested:—A drench of raw linseed oil, 1½ pints; turpentine, 4 tablespoonfuls. Enemas of warm soupy water every three hours. Further, give a teaspoonful of powdered nux vomica three times daily (to give—mix with treacle and smear on the tongue). (2) The following treatment is advised—give the following drench:—Epsom salts, 1½lbs.; ginger, 4 tablespoonfuls; treacle, 1 cupful; warm water, 2 pints. Subsequently give a teaspoonful of powdered nux vomica night and morning (as above) for 10 days. Further, feed on good quality chaff and bran, and give 1lb. of linseed meal daily. Give green feed, if available, and also a handful of sterilised sweet ground bonemeal mixed in the damped feed three times weekly.

TOBACCO CULTURE.

[By R. C. SCOTT, Supervisor of Experimental Work, and S. B. OPIE, Field Officer.]

The area under tobacco in Australia has fluctuated very considerably during the 75 years in which this crop has been cultivated. During the Civil War in America, when leaf imports into the Commonwealth were greatly restricted, the area under crop rapidly increased, and in 1888-89 almost 7,000 acres were devoted to tobacco. However, this condition has not been maintained, and of recent years the area planted has varied from one to three thousand acres. The reason for this decline is that the public taste has changed from the heavier smoking tobaccos to the light smoking type suitable for cigarettes and mild smoking pipe tobaccos. In order to meet this demand, manufacturers have had to secure light leaf and discourage the production of dark, air-cured leaf which hitherto was in demand. Accordingly, in 1919 an ultimatum was issued to the growers by manufacturers intimating that they were no longer prepared to purchase unlimited quantities of this class of tobacco. They recommended growers to aim at the production of light, fine-textured leaf, and to cure the leaf under controlled temperature in proper barns erected for the purpose.

From that time the whole character of the industry in Australia changed, and to-day it is essential that light colored, mild smoking flue-cured tobacco must be produced in order to become saleable. That there is ample room for expansion in this industry provided that quality leaf is secured is indicated by the following figures showing the production and consumption of tobacco in Australia for the year 1928-29. In this year the tobacco imported into the Commonwealth amounted to 23,072,691lbs., whilst that produced totalled only 1,808,160lbs. The relative figures for other seasons are practically the same, showing that Australia only produces from 8 to 10 per cent of its requirements for tobacco. There is little doubt that Australian leaf possesses characteristic flavors and aromas, but it can be confidently claimed that these are not objectionable. Certainly they are not acceptable to every smoker, but no more so than various brands of imported tobaccos. It is therefore a matter of individual taste. Other things being equal, the average smoker will not be dictated to as regards taste.

However, price is the most important factor in determining the popularity of a tobacco, and the position to-day is that Australian tobacco possesses an advantage over imported tobaccos in this respect. Further, within recent months the financial position has compelled smokers to economise and adopt brands containing locally grown leaf. In the majority of cases they have quickly acquired a liking for the characteristic flavors of this leaf and an appreciation of the quality. This augurs well for the future, and there is every reason to anticipate rapid and successful development of the tobacco industry in Australia.

HISTORY OF THE CROP IN SOUTH AUSTRALIA.

Many of the older residents can recall the cultivation of tobacco by Chinese some 30 to 40 years ago, but it was not until about 1920 that the production of bright tobacco was attempted in this State. Following a visit from Mr. Temple A. J. Smith, Tobacco Expert in Victoria, who expressed the opinion that certain districts should be able to produce leaf of the necessary quality, a number of experimental plots were planted during the season 1920-21. These plots extended from Williamstown to Ashbourne in the Adelaide Hills, and also in the Inman Valley. The results obtained were rather encouraging, the best crop being that raised by Mr. W. E. Daddow at Mount Barker. The yields and prices secured aroused interest in the possibilities of tobacco in this State, and in succeeding years other landowners took up the cultivation of the crop. However, the expansion has not been rapid, because of the high values obtained for

other forms of agricultural produce, the necessity for experience in handling the crop, the need for special curing barns, and the irregularity of our summer rainfall. However, consequent upon the fall in price of other agricultural products, the possibilities of tobacco growing is commanding attention at the present time, and larger areas will be planted in future years.

The following table indicates the area of tobacco planted in South Australia since 1920:—

| Year. | Area. Acres. |
|------------------|-----------------|
| 1920-21 | 1 |
| 1921-22 | 1 |
| 1922-23 | 1 |
| 1923-24 | 10 |
| 1924-25 | 36 |
| 1925-26 | 11 |
| 1926-27 | 27 |
| 1927-28 | 17 |
| 1928-29 | 14 |
| 1929-30 | 37 |
| 1930-31 | 80 (estimated) |

Crop of Tobacco.

PROSPECTS OF THE CROP IN SOUTH AUSTRALIA.

In the succeeding pages the requirements for successful tobacco cultivation are indicated.

It would appear that there are considerable areas in this State which answer the natural requirements, the only doubt being whether we have a sufficiently regular and adequate summer rainfall. However, in many localities this disadvantage can be overcome by the provision of irrigation water, thus ensuring regular crops independently of the rainfall recorded. Given intelligent application of the principles governing the production of light flue-cured tobacco, followed by the improvement in methods which will be gained as the result of added experience, it can be confidently predicted that tobacco culture will become an important and profitable crop in South Australia.

Emphasis must be placed on the fact that every prospective grower must be prepared to give full attention to the crop if maximum prices and good quality leaf are expected.

NATURAL REQUIREMENTS FOR THE PRODUCTION OF BRIGHT, FLUE-CURED LEAF.

Soils.—The character of the soil has the greatest influence on the production of the lighter and brighter types of tobacco. It is generally accepted that if this class of leaf is to be secured, rich soil must be discarded in favor of light, sandy soil.

Tobacco will grow on a great variety of soils, but as the grower must supply the manufacturer with the type of leaf required by the consumer, it follows that as the demand to-day is for a light smoking tobacco, the producer must plant his crop on land of such character as to yield leaf of the necessary quality. Soils which are very retentive of moisture or in a high state of fertility, tend to produce dark, heavy leaf of comparatively high nicotine content. Such leaf is not required by the manufacturer. The soil suited for the production of bright tobacco is of a sandy nature, naturally well drained and overlying a good subsoil, preferably yellowish in color.

To counteract the effect of water-logging after heavy rain, the sand should be fairly deep, a depth of approximately one foot being desirable.

Typical tobacco soils of South Australia were examined by Mr. E. P. Bainbridge, Assistant, Australian Tobacco Investigation. His description and mechanical analyses of the land at that time under crop were as follows:—

“The soil used for tobacco is apparently derived from a fine grained ferruginous sandstone. The country is hilly, and the land used mainly is on the gentler slopes and in the valleys. The soil is mainly a very fine sandy loam, light grey or white in color, and 9in. to 18in. deep overlying a yellow or red sandy clay. In places there is a large amount of ironstone and quartz concretions in the soil. Sometimes these appear on the surface, but often they are in a definite layer in the soil. The clay is free or almost free from them.”

| Depth of Sample :— | Mount Barker. | | | Macclesfield. | | |

| Moisture | 0.5 | 0.5 | 6.3 | 0.6 | 2.6 | 2.3 |

Situation.—As a rule the higher and moister areas provide the best conditions for ripening leaf, whilst the dryer districts, even when the plants are adequately supplied with irrigation water, do not tend to produce leaf of the same quality or aroma.

In the view of some, sea air has an injurious effect on flavor, and it is sometimes advocated that tobacco should not be grown in close proximity to the sea. On the other hand, in some countries of the world first class leaf is produced when grown close to the waters' edge. It would appear, therefore, that whilst sea air may have a bad influence on flavor, it is not likely to be a serious objection except perhaps where the arrangement of hills or cliffs subject the crop to frequent salt-laden winds.

Climate.—Climate is the factor affecting the flavor of tobacco leaf. For best results the crop should grow regularly and fairly quickly. Any check in development, such as may be caused by a comparatively long, dry period, or by cool weather, will tend to affect quality. Whilst tobacco thrives under moist soil conditions, it quickly suffers in the presence of excess water. If we could be sure of regular precipitations there are a number of areas in this State with sufficient rainfall for the cultivation of tobacco. However, experience has shown that rains during the growing period of the crop: that is to say, during the summer months of the year, are often received in heavy falls, with a space of some weeks intervening between one soaking and the next. Such distribution is not in favor of quality leaf, and we must face the fact that for regular yields and the

production of light, bright tobacco, a supply of irrigation water would be of very great assistance. Any new grower should endeavor to commence operations in areas where irrigation could be applied if the necessity arose. In a general way, it may be said that any district receiving an average fall of from 40 points to 50 points per week during the growing period of the crop offers possibilities for tobacco cultivation. This amount, however, is considerably less than that obtaining in other tobacco producing countries, where it approaches an average of approximately one inch per week.

At Mount Barker the mean summer rainfall recorded over the past 69 years is as follows:—

| | |
|--------------------|------------|
| October | 281 points |
| November | 156 “ |
| December | 132 “ |
| January | 102 “ |
| February | 94 “ |
| <hr/> | |
| Total | 765 “ |

Tobacco Plant Showing Typical Leaf Growth.

With regular distribution this may be regarded as a very satisfactory rainfall for tobacco, and the prospects of successful cultivation without having to resort to irrigation will vary according to whether that recorded for any season is above or below the figures quoted. In the same way those districts enjoying a higher rainfall than Mount Barker possess an advantage in this respect. However, as has been pointed out, our difficulty is the irregularity of distribution rather than the lack of total quantity. This renders means to irrigate an insurance against comparative failure.

Frosts are liable to cause considerable damage, more particularly early autumn frosts before the leaf has been harvested. Tobacco is more resistant to attack than such crops as potatoes, maize, or tomatoes, and is rarely seriously affected by late spring frosts. However, low temperatures experienced during February, March, or early April may ruin matured leaves. It follows, therefore, that districts and fields must be chosen which are reasonably free from frosts in late summer or early autumn.

It is easy to realise that tobacco leaves may be considerably damaged by the action of wind. A sheltered position should always be sought, and if this is not possible, wind-breaks should be provided by planting rows of maize at right angles to the direction of the prevailing wind or the erection of brush fences.

DESCRIPTION OF THE PLANT.

In tropical countries the tobacco plant is a perennial, but in the more temperate parts of the world many plants are killed by frost and the cold wet weather of winter, with the result that it usually becomes an annual so far as commercial leaf production is concerned.

The species commonly grown is *Nicotiana tabacum*. This type grows from 2ft. to 9ft. in height, with spreading leaves varying in shape from ovate to lanceolate according to the variety. The leaves are arranged spirally round the central stem, the distance apart on the stalk varying considerably, but usually about 2in. The flowers are held in clusters, the corollas being bell-shaped, about 2in. long, and reddish to pinkish-white in color. Another species introduced into South Australia for trial is *Nicotiana rustica*. It is a hardy type, with ovate leaves on long stems, and with greenish-yellow flowers. The Turkish tobacco is probably of this species. However, it does not appear likely to prove of commercial value in Australia.

VARIETIES.

Botanically the varieties being grown in Australia belong to the species *Nicotiana tabacum*. They may be divided into two types, namely, Broad-leaved Virginian and Burley. Both of these are suitable for the manufacture of light plug and cigarette tobacco. The Virginian type is the more popular. It suits the majority of our tobacco soils, and is fairly hardy. It is usually flue-cured.

The Burley type when grown in other parts of the world is largely air-cured. It is used for the production of characteristic brands of tobacco such as Temple Bar, Edgeworth, &c. It possesses the advantage of producing good colored leaf even when grown on heavy and more fertile soils. Whilst not largely grown as yet, it appears to us to be a valuable type for many of our South Australian soils, and one which every grower should test on his class of tobacco land.

Amongst the best Virginian varieties are:—

Warne.—Probably the most widely grown in this State, and suited to the lighter soils.

White Stem Orinoco. } Good varieties which yield bright, fine quality leaf when
Little Orinoco. } grown on medium to light class land.

Hickory Prior.—A good quality tobacco for soils slightly heavier in type.

Numerous other varieties have been tested, and the following may be listed as being satisfactory:—Adecock, Broad Leaf Gooch, Big Orinoco, Cash, Conqueror, Dungowan, Gold Leaf, Hester, Jamaica, Lacks, Long Leaf Gooch, Spotted Gum, Yellow Orinoco, Yellow Prior.

Burley tobaccos of promise are:—Judy's Pride, Standing Resistant, Station Stand Up, Vimond Kelly, and Kelly.

These varieties are suited to the richer soils or land containing more clay than that recommended for Virginian tobaccos. They color up well in the field, but are rather susceptible to disease and insect attack.

Within recent years the Department has introduced a number of varieties from the more temperate countries of the world, in the hope of obtaining a type better suited to local climatic conditions. These have not been tested for sufficient length of time to be able to make a definite statement regarding their value, but a limited number show promise of yielding good quality leaf.

POSITION OF TOBACCO IN ROTATION.

Tobacco is not a particularly exhausting crop, and provided it is adequately manured, may be continuously grown on the same piece of land until disease, pests, or fouling renders a change of crop necessary. Continuous cropping is largely adopted in some countries, but is not to be recommended for our conditions. At times a second or even a third crop may be removed from the same piece of land in successive seasons, without danger, but if possible a rotation should always be planned.

Tobacco does not follow potatoes with advantage, because this crop tends to deplete the land of potash, an important plant food for tobacco. It should preferably be preceded by a leguminous crop in order that the soil be well supplied with humus, but in such case it is essential that all organic matter be ploughed under several weeks before planting, and so become thoroughly decomposed.

In our Adelaide Hills districts it is recommended that the tobacco crop should be followed by Subterranean clover and left down to pasture for at least one season.

Departmental Experimental Area, Mount Barker.

PREPARATION OF THE FIELD.

Tobacco does not thrive in a sour soil, and therefore the field selected should preferably have been cleared and under cultivation for some time.

If new land recently reclaimed from timbered conditions is to be utilised, it should be prepared some months before planting in order to allow the soil to sweeten. If possible, however, new land should carry some other class of crop before being planted with tobacco. Tobacco is a summer-growing crop, and as our summer rainfall is limited and irregular, it follows that every endeavor should be made to place the soil in such condition that it will absorb and retain the maximum amount of winter rainfall.

If there is little danger of the land washing, it should be ploughed on a fairly deep furrow, in late autumn or early winter. In many districts, however, this is not advisable, and ploughing must be postponed until early spring. The first ploughing should be relatively deep, 8in. to 9in., followed by a second shallower working later in the

season, and sometimes a third shortly before planting. According to the soil requirements the land should be cultivated, rolled, and harrowed, so that moisture is retained and weeds kept in check. At transplanting, the surface should be in a fine, free condition, and the under layers well compacted.

MANURES AND MANURING.

Tobacco needs to be liberally but judiciously fertilised, as excess food, particularly nitrogenous, affects the quality of the leaf. The manurial requirements of tobacco can be indicated in a general way, but the actual amounts which it is economic to apply can only be determined by field experiment, and will vary within fairly wide limits. The most important plant foods are nitrogen, phosphoric acid, and potash. Lime may be included as an important soil amendment, as tobacco does not make good growth in sour soils. An application of this material is necessary to improve such lands. On the other hand, fertilisers containing chlorine are to be avoided, as according to the majority of experiments this substance affects the burning quality of the leaf. Most local soils are well stocked with available nitrogen, fairly well supplied with potash, but markedly deficient in phosphoric acid. However, tobacco needs abundant supplies of readily available foodstuffs, and therefore, notwithstanding the presence of nitrogen and potash, most tobacco manures include limited quantities of these two substances. Phosphoric acid, apart from its action as a plant food, encourages root development, thus rendering the plants more drought resistant. It hastens maturity, which allows the crop to ripen in good weather and yield good coloured leaf. Nitrogen is a relatively dangerous fertiliser for tobacco, since when present in excess it delays ripening, causes dark green fleshy leaves, which cure out to dark colored, coarse-textured tobacco of high nicotine content. Potash improves the texture of the leaf and promotes good burning qualities. Muriate of potash or kainit should not be utilised, because of the chlorine they contain. Lime is necessary for sour or acid land. When used in the form of air-slaked lime or crushed limestone, a dressing of at least 1 ton to the acre is required. This quantity should be spread over the surface of the ploughed land and harrowed in.

The fertilisers phosphoric acid, nitrogen, and potash are available from manufacturers in the form of a complete fertiliser. The percentages of each will vary according to the purpose for which it is intended, and for tobacco the combination may include:—

- 8 to 12 per cent. phosphoric acid
- 3 to 6 per cent. nitrogen
- 2 to 6 per cent. potash.

The phosphoric acid is usually present as superphosphate, the nitrogen as nitrate of soda, sulphate of ammonia, or dried blood, and potash as sulphate of potash.

A complete fertiliser on the market in this State, and recommended for use in applications of from 7cwts. to 10cwts. per acre, has the following analysis:—

- 8 per cent. phosphoric acid (17½ per cent. water soluble phosphate)
- 2 per cent. nitrogen
- 5 per cent. potash.

APPLICATION OF FERTILISER.

Comparatively heavy dressings of manure must be given to tobacco to have appreciable effect. The methods of application vary. The fertiliser may be broadcast or drilled over the area shortly before planting; applied at the same time as the young plants by means of the transplanting machine, or spread around the base of each seedling. A combination of these methods is recommended, namely, about two-thirds of the manure to be drilled or broadcast immediately after the last ploughing. About half the balance applied at planting time, either by hand or machine, and the balance to which additional nitrogenous manure has been added spread around the seedlings about two to three weeks after planting. This last fertilisation is usually at the rate

of $\frac{1}{2}$ oz. to 1 oz. of manure per plant. If a planting machine is not available for distributing the fertiliser with the plants, a drill may be utilised by sowing the manure through two hoes only and blocking the intervening space of three to four hoes between each pair. The optimum manurial dressing will need to be ascertained by experiment. On the average, 10 cwt. of superphosphate if used alone, or about 8 cwt. of complete fertiliser per acre will not prove excessive.

SEEDBEDS.

Tobacco seed is extremely small, and it is therefore necessary to raise the seedlings in nursery beds, and later transplant in the field. The raising of the tobacco plants is one of the most important operations in the cultivation of this crop, and for this reason is given in some detail. It is easy to realise that at transplanting time the grower must have available an ample supply of strong, healthy seedlings if his young crop is to secure an even and vigorous start. The establishing of a field of tobacco under our climatic conditions is one of the most difficult operations, and success is largely dependent upon the class of seedlings planted.

SITE.

An area of good quality soil should be selected for the seedbed, and of such physical nature as to allow for rapid drainage of surplus water. In this connection the placing of the seedbed on gently sloping land is an advantage. The position should be conveniently situated, as the beds must have regular attention. At times as many as three to four waterings are necessary daily. Arrange the beds so that they receive the maximum amount of sunlight, particularly regarding that of the early morning. Do not place them near large trees, whose roots will deprive the young plants of food and water. Shelter also is of advantage, and if a naturally protected area is not available, a brush fence built around the beds will be well worth the time and trouble incurred in erection.

PREPARATION.

Having chosen the site, clear the surface of all rubbish, and thoroughly dig the whole area, including pathways. This digging should be done in autumn or early winter. The seedbed needs to be placed in a high state of fertility, since the young germinating plants quickly exhaust the food stored up in the minute tobacco seeds and are then dependent upon the food supplies which the tiny rootlets are able to extract from the soil. For this reason a heavy application, 30 to 40 tons per acre of well rotted farmyard manure should be dug under. Throughout the winter the land should be kept in a good state of tilth, and all weeds destroyed. In August or early September the nursery may be formed by marking off the area into beds and pathways. The beds should be comparatively narrow, about 3 ft., so as to facilitate weeding, &c. The pathways may be of any convenient width, but it is a mistake to make them too narrow. The same width as the beds is not excessive. The surface soil from the pathways is removed and thrown on to the adjoining beds, thus raising the level by several inches. This assists drainage, and allows for healthier plants if wet weather should be experienced. The surface of the beds should be well worked down to a fine tilth.

STERILISING.

In order to destroy disease spores, injurious pests, and weed seeds which may be present, it is customary to sterilise the surface soil of the seedbeds by burning, fumigating, or steaming. This is a common practice with nurserymen, where a special apparatus is utilised for treating seedbed soil. With the tobacco grower, however, these facilities are rarely available, and he is usually compelled to adopt the practice of burning in a comparatively rough, but economical manner. This treatment of the

seedbed is not absolutely essential, but it is well worth the trouble involved in rendering the soil free from weeds, &c. When sterilising by burning, the operation is carried out shortly before the sowing of the beds. Timbers of about 2in. to 3in. in diameter are placed across the bed about 2ft. apart. These keep the fire directly off the soil and allow for better burning. Upon the timber, brushwood is piled to a height of 3ft. to 4ft., thus providing sufficient fuel for a good fire to burn for about half an hour. The fire is lit on the leeward side to allow for a steady burn and good sterilisation of the surface soil to a depth of from 3in. to 4in. The charred and unburned timber is raked off, and on the ashes a light dressing of well rotted farmyard manure free from weed seeds is spread. The seedbed is then well raked to a depth of about 2in. as a final preparation before sowing. If good farmyard manure is not available, equal weights of bonedust and blood manure should be added at the rate of about 3cwts. per acre respectively. Formalin is utilised for sterilisation by fumigation. A 2 per cent. solution is applied by means of a watering can at the rate of half a gallon per square foot. Immediately after treatment, bags or other covers must be placed over the surface to hold the fumes in the soil. The operation may be carried out in autumn or shortly before seeding. The latter is to be preferred, but care must be taken to see that at least a fortnight elapses between treatment and

Tobacco Seedbeds at Penola.

sowing, as otherwise a poor germination is likely to result. Formalin treatment of the seedbed is recommended for the prevention of fungoid diseases.

Steam sterilising is popular in some countries, as the bed may be sown immediately after treatment. Special apparatus is necessary, by which steam is forced under an iron cover about 6in. in depth, placed on the surface of the soil. The steam is applied at definite pressure and maintained for a certain length of time, when in most soils it will have penetrated to a depth of about 6in. The beds are then seeded without further tillage.

Before commencing sowing, the seedbeds should be boarded round with timber, preferably about 1ft. in height, on which the protective coverings will be placed. The area of seedbed required will need to be determined. In this connection, provision should be made for twice, or even three times, the area necessary to supply seedlings for a single planting. The young plants must be in the correct stage of development

at transplanting time. Transplanting may extend over several weeks because of unseasonable or other causes, and if only one seeding is made the late-sown plants are too old for best results. Therefore, three seedings each sufficiently large to supply plants for the whole field is strongly recommended. Each should be spaced at intervals of 12 to 14 days, so that good plants will be available over a period of six to seven weeks. This allows for good selection for filling misses, and is a safeguard against such accidents as frosts or disease wiping out the earlier sowings.

In the Adelaide Hills, September is the usual seeding month, the first sowings taking place in late August, and late sowings towards the end of September or early October. Occasionally even later sowings may prove satisfactory, but are not advisable.

Tobacco seed is extremely small, and approximately 1,000,000 would be required to weigh 3ozs. However, their fertility is low and only 60 to 70 per cent. are capable of germinating. With satisfactory seedbeds, 1oz. will provide sufficient seedlings for about seven acres of land. An area of 100 square feet of seedbed is required per acre of land intended for planting. This necessitates one-seventh of an ounce, or one teaspoonful of tobacco seed. When seeded at this rate, the plants are well spaced and

Glass-covered Tobacco Seedbeds.

strong seedlings provided, whereas thicker seeding causes much additional work in thinning out, if weak, spindly plants are to be avoided. In sowing, the seed is mixed with a liberal quantity of some medium, such as ashes, pollard, sand, &c., so that the small quantity required may be spread evenly over the surface. In order to ensure regular distribution, the mixture for any given area should be halved, and one portion sprinkled over the seedbed travelling up and down. The remaining portion should then be spread with the sowing direction moving at right angles to the first. Under this method two sowings are made over the same area and a more even seeding secured. Only very shallow burial is required, and raking should be avoided. Patting with a flat board will press the seed into the ground to a sufficient depth. Deep covering is a frequent cause of unsatisfactory germination. The bed should be watered lightly, using a fine spray nozzle and keeping the soil moist, but not too wet. Careful attention is essential at this stage, and in warm weather light waterings may be necessary three to four times each day. With favorable temperatures, germination will occur in a

few days, but under cold conditions may take as long as six weeks. The minute plant and tiny rootlets are buried just under the surface soil, and therefore if this is allowed to become dry, the young plant will die, whilst on the other hand, excess water leads to drowning.

COVERINGS.

The coverings should be placed over the seedbeds immediately after the tobacco is sown. These are necessary to protect the beds from frosts, rough weather, and to a certain extent from insect pests. They provide for more uniform temperatures and create a warm condition conducive to rapid growth of plants. A number of materials are used for protective coverings, such as glass, hessian, cloths, boughs, &c., which by means of the supports surrounding the beds provide a cover held about 9in. to 12in. high above the surface of the soil. Glass frames offer certain advantages in that they protect the beds from heavy rains, maintain warm temperatures, and hasten plant development, with the result that seedlings raised under them are ready for transplanting from one to two weeks earlier than when grown under other covers. On the other hand, they are expensive and need removing or sliding along for watering of the beds. Hessian is quite a satisfactory covering. The side protection is the same as

Cloth-covered Tobacco Seedbeds.

for glass, with two or three wires run lengthwise along the beds to support the hessian. Cloth consisting of waterproofed calico is also used to a limited extent. The waterproofing is done by treating in a soap bath (1lb. to 1gall.) and then in a solution of alum (1lb. to 1gall.). The calico is allowed to remain in the soap solution for about half an hour, wrung out, then soaked in the alum solution, and rinsed in clean water. The material becomes quite waterproof, is tacked to frames, and is a very suitable covering. Boughs are spread over wire-netting suspended above the beds, whilst occasionally wattle sticks are placed thickly side by side about 1ft. above the surface soil. The hessian, boughs, and stick covers do not protect the beds from heavy rain, which may saturate the soil and cause very slow plant growth. Other forms which will keep off the rain prevents this soil coldness and usually produce earlier plants. On the other hand, with glass and fabric coverings, care is necessary to see that the

beds receive proper ventilation. During hot days lack of ventilation may result in the scalding of the plants. To overcome this danger, the frames should be gradually raised as required, increasing the space as the weather becomes warmer.

SEEDLINGS.

The beds should be kept well weeded, and, if necessary, the young plants thinned out to about 70 or 80 to the square foot. If they are not making satisfactory headway, it may be necessary to force them along by applications of liquid manure. However, the effect of such applications should be carefully noted, as they may tend to burn the delicate foliage. For this reason, liquid manure should not be applied until the plants have made their fourth leaf. A suitable liquid may be made up by dissolving 1lb. of nitrate of soda or sulphate of ammonia in 10galls. of water. This quantity is sufficient for 100 square yards of seedbed. After applications it is advisable to water the beds, so as to wash the manure from the leaves, and thus reduce the danger of burning. A second treatment may be necessary, but at least a fortnight should elapse between one application and the next. Liquid manure may also be obtained by about half filling a barrel with cow dung and then filling with water. The mixture is stirred at intervals, and let stand for a week. When applying, it is diluted to a strength of 1gall. to 4galls. of water, and used at the rate of from 2 quarts to 3 quarts per square yard.

Hardening off Tobacco Plants.

The plants may be ready for transplanting in about seven to eight weeks after germination, but with more open beds and lower temperatures a much longer period is required. When the plants are about 4in. to 5in. in length they are ready for setting out in the field. If smaller, they are more delicate and do not establish themselves so readily, whilst old seedlings make poor plants, tending to run to flower whilst still quite small. It is obvious that the seedlings should not be removed from the protected seedbeds to the open field without preparation.

This preparation is termed hardening off, and consists of forcing the young plants to become accustomed to more severe conditions, so that the shock of transplanting is not felt to the same extent. When the plants are well established in the seedbed, the watering is limited and only applied when the leaves show signs of wilting. About a fortnight before transplanting is anticipated, the covers are removed, commencing with removal for a few hours, and gradually extending the time until they may be left off altogether. In this way the plants are gradually exposed to open air conditions and do not suffer the same setback as would be the case if set out in the field without being hardened off.

(To be continued.)

DRYING STONE FRUITS.

[A paper read by Mr. A. Rogers at a meeting of the Clare Branch of the Agricultural Bureau.]

The question of preparing stone fruits for drying presents many difficulties to laying down hard and fast rules. For instance, fruit grown under dry conditions needs somewhat different treatment to that which has developed under ideal conditions. First in order, and perhaps the most important, is the apricot. Excellent fruit can be spoilt by careless handling, whereas very ordinary fruit can be brought up to a good marketable article with scientific methods. Allowing that we have well-grown apricots to start on, the first question is, "In what stage of ripeness should they be picked?" The term "eating ripe" is generally used, but that permits a deal of variation, from practically green, to mushy ripe, according to taste. The apricot should be left on the tree so long as it can be handled without crushing in the containers. If petrol tins are used, I prefer to open on the sides; it gives a greater surface and does not damage the fruit so readily. Different methods of splitting the fruit in question can be used, but most in favor is the passing of a sharp knife around the sutural line, being careful that the whole of the flesh is cut—not torn—in the operation. The even cut prevents the loss of syrup during sulphuring, and adds to appearance. The fruit should be opened and transferred to the sulphur-box as quickly as possible. Where practicable, overripe fruit should be discarded or sulphured separately. Overripe fruit absorbs sulphur-dioxide more readily than firm, and if sulphured together, gives an unsatisfactory product. Unripe fruit that may have been accidentally picked may be improved by stacking on trays for a day or so, but this will not make a top-grade product. It is recommended that fruit should be stacked from the bottom upwards in the order in which it is cut. Freshly cut fruit absorbs sulphur-dioxide more readily than that opened some time prior to sulphuring. This arrangement of stacking allows the driest fruit to be in contact with the maximum density of warm sulphur fumes, thus tending to uniform sulphuring results. While this might be good, I would rather depend on spraying the fruit with clean water. On a hot drying day I spray each tray of fruit as it goes into the stack, giving the first pitted the heaviest spraying. I also spray the stack when completed, as well as the ground around, to create a humid atmosphere. Lower the hood immediately and fill around the bottom with damp sand. If possible, trays with a smooth surface should be used in order not to mar the surface of the fruit. If anything special is required, dry on glass. Trays should be hosed before fruit is placed thereon.

TYPE OF SULPHUR CHAMBER.

Many types of sulphur chambers are in use, but most in favor is the movable hood. They hold an advantage, in that the large sulphur-house takes so long to fill, and if not full, makes the sulphuring more difficult to gauge. Any number of hoods can be used, and they are not very expensive to build. The hood I have in use has an air space of 70 cubic feet, taking 17 5ft. x 2ft. trays, carrying 3½cwt. of split fruit. For the frame, I used 3in. x 1½in. Oregon (joiner's) and covered these with pressed paper. I have had this in use four seasons, and find it stands the sulphur fumes very well. It makes a hood practically airtight and no vent hole is needed with the method of sulphuring I employ.

PREPARING SULPHUR FOR BURNING.

The method often followed is to place coals of fire in a pan, and throw on a given quantity of sulphur.

Sulphuring Apricots.—The regulations in force here and in England regarding the amount of sulphur-dioxide permitted in dried fruit, makes it necessary to keep it below 14 grains per pound and still provide a marketable product and of good color. The accepted quantity of sulphur is from 6lbs. to 8lbs. per ton of pitted fruit, but the weather conditions make a little difference. On a cold, windy day a little more sulphur is needed than on a hot sultry day. That difference, however, is usually corrected by the length of exposure. For sulphuring I have a pit immediately under the trays about 18ins. deep with a channel leading to the outside of the sulphur box, and covered, forming a trap door for convenience in attending to the sulphur-pan. I use 1½lbs. of prepared sulphur to 3½cwt. of pitted fruit, putting in half when closing down, and the remainder two hours later.

PERIOD OF EXPOSURE.

Under average summer day temperatures four to six hours should be sufficient to preserve the color without over-sulphuring. On very hot days, four hours would be long enough. The practice of leaving the fruit in the sulphur chamber over night is not advocated. It may result in over-sulphuring. Also, if left in over night you may find that the syrup (with which the cups are partly filled, and in some cases completely filled), instead of being quite clear, is covered with a milky sulphur residue. When the fruit is not taken out before night, I make a practice of raising the hood a few inches to allow the fumes to escape. If there is any suspicion of over-sulphuring, the sulphuric-dioxide content may be reduced by stacking trays for a day or two. Upon removing from the sulphur chamber, I spread out the fruit for a day to dry up the syrup and make the color secure, after which I prefer to dry in the shade.

When the fruit is dry enough to remove without damaging, three or four trays may be put in one, and again stacked up to finish drying. In that way you have less trays in commission. Fruit such as apricot, peach, nectarine, and prunes that is to be stored and dressed later I allow to become very dry. In that state, it can be immersed in a boiling dressing for a longer period and so destroy any eggs, larvae, or more advanced stage of fruit grub.

OTHER ADVANTAGES.

It is possible to sweat and pack such fruit straight away, whereas fruit on the damp side might have to be put out again to dry. This is to be avoided, for the sun takes off the gloss. Some growers seem to think too much weight is lost by thoroughly drying their fruit, but it is surprising how little moisture it takes to bring it back to a nice, pliable condition. After all, it is sugar that makes for weight. Peaches and nectarines are treated in much the same way as apricots. All dust should be removed from peaches, and, if necessary, hosed before opening.

Of nectarines, the Goldmine is the most favored. Well-shaded fruit without much blush is to be preferred for drying, but the point should be stressed that nectarines of all other fruit must be allowed to ripen on the tree, otherwise they wilt and become bitter.

As a special when the nectarines are opened, put a little sugar in each cup before going into the sulphur chamber. Care must be taken to keep fruit so treated away from ants whilst drying. Nectarines treated in this way and dressed supply an excel-

lent adjunct to the list for dessert. For cooking, we again come to the point of being ripe to facilitate the removal of the skin. I do not know if the practice of removing the skin is general. If not, I make the following suggestion:—Put fruit in saucepan, over which pour one quart of boiling water, add one teaspoonful of carbonate of soda, put on lid, and stand aside for 20 minutes, when skins can be easily removed; after which cook as desired. Unripe fruit does not respond so well.

TREATMENT OF PRUNES.

Treatment of prunes is far more simple. The lye for dipping is usually 1lb. caustic soda to 25galls. of water for well-grown fruit. In the case of prunes grown under droughty conditions, which tends to make the skin tough, more caustic soda should be added.

I prefer to add more caustic soda rather than dip for a longer period to obtain the desired amount of cracking of the skin. The dip should not be allowed to go off the boil. Another practice is to prick the surface of the fruits. To do this latter, pricking boards are used. A shute is made, and the bottom is evenly covered with plaster of paris, and while it is yet soft, pins are placed in it so that about one-quarter of the point projects upwards. They must be close enough to prevent the fruit from lodging between them. The prunes are allowed to run down the shute on to the trays and are then ready for placing in the sun. The practice of dipping is most in favor. D'Agen should be left on the trees until they will shake down, but they will not respond well to dipping if left lying in the hot sun for any length of time.

Robe de Sargent and Splendor especially should be picked off the trees to obtain good results in dipping. My experience with Splendor has led me to consider that a light dip is most satisfactory. Severe cracking of the skin on Splendor prunes allows too much of the pigment to come out, and results in a russet color when dry. If yellow plums are being dried, they should be subjected to sulphur fumes for about eight hours after dipping to preserve the bright golden color of the fruit. After dipping the prunes and plums, spread out to dry off, then stack up and finish drying.

SILVER LEAF.

[By E. LEISHMAN, Horticultural Instructor, Mount Lofty Ranges District.]

Attention has been drawn for several years in the Hills district to the silvering of the leaves of the plum and to a lesser extent the cherry and apple trees. I have made frequent observations on trees so affected, but until this season no definite evidence has been procured to show that the cause was due to the bracket fungus (*Stereum purpureum*).

Fructing bodies of Fungus (*Stereum purpureum*) found on an apple tree at Carey's Gully.

With Mr. S. D. Garrett, Assistant Plant Pathologist at the Waite Agricultural Research Institute, I made an inspection in an orchard situated at Carey's Gully, where the silvering of the leaves appeared on plum, cherry, and apple trees.

Fructifications of this fungus were found on the plum; although not present on the apple and cherry, it was probable that they were attacked by the same fungus. Since this visit to this orchard, I have located fruiting bodies of this fungus in orchards at Forest Range, Bridgewater, and Carey's Gully on plum and apple trees.

SYMPTOMS.

Usually, in the beginning, the disease is confined to a single branch or twig, causing the leaves to assume a silvery hue approaching the colour of lead. The branch showing this affect generally dies, and from year to year other branches are affected until the whole tree is involved. Probably three to six years elapse before the tree is wholly killed. The silvering of the leaves is claimed to be due to the secretions of toxins by the fungus in the stem. On the dead limbs and trees the fruiting bodies of this fungus appear. This bracket fungus may be distinguished by the fact that the inner spore bearing surface or hymenium is always quite smooth of a lilac to purple color. Where leaf silvering due to this fungus occurs, a brownish discoloration of the wood towards the base of the branch is always found.

CONTROL.

Stereum purpureum is a wound parasite and can cause infection only through wounds due to pruning, bruising the bark of limbs, and breaking off of branches. Trees affected with this fungus do not always die; young and vigorous trees may occlude the fungus by the formation of an impenetrable gum barrier around the invaded tissues.

Resistant varieties are those in which this gum barrier is most readily formed. During the summer months (June, July, and August) in England all varieties of plums exhibit this gum reaction so strongly that no infection can occur. The usual measures of fruit disease control do not apply to "Silver Leaf," therefore precautionary means should be taken.

Mr. S. D. Garrett, who had an opportunity to observe work in this connection in England under Dr. F. T. Brooks, recommends the following control:—

1. All wounds should be protected as soon as possible by covering either with soft grafting wax or an antiseptic thick paint, made up as follows:—To 2lbs. of white lead paste (as bought), add two teaspoonfuls of paste driers and two tablespoonfuls of linseed oil. Mix, then add two tablespoonfuls of turpentine and mix well.

2. By the Silver Leaf Order of 1923, English growers are compelled to destroy before midsummer all dead, woody tissues capable of harboring the fungus, meaning not only dead branches actually on the trees, but all dead wood lying about the orchard.

By cutting out dead branches shortly before mid-summer (July 15th in England) the risk of re-infection through wounds thereby made is reduced to a minimum, for the spores of the fungus are then least abundant. It is exceedingly difficult for the fungus to cause infection at that season.

3. In the early stages when the silvering is confined to a few branches, the disease may be controlled by cutting these out early in the summer. Care must be exercised to cut back well beyond the limit of the discolored wood however, otherwise the operation will have been useless. There is, however, a chance that with young and vigorous trees silvered branches may recover. The chances of natural recovery may be materially increased by careful manuring.

The importance of painting wounds with an antiseptic paint after pruning operations has always been advocated as a precautionary measure against fungus diseases. Definite proof that the Silver Leaf disease is in the district should stress the importance of the operations, such as destroying dead limbs, more especially in orchards where Silver Leaf has appeared.

This fungus was determined from portions of an old apricot tree carrying "silvered" foliage in an orchard in the Clarendon district by Mr. G. Samuel, of the Waite Institute, some four years ago. Mr. Geo. Quinn (Chief Horticultural Instructor), who discovered the specimens, was able to secure the fructifications of the fungus at the same time.

THE MARKETING OF AUSTRALIAN EGGS OVERSEAS.

A recent report issued by the Department of Markets indicates that the 1930 egg export season has been the most successful one since compulsory grading and supervision were adopted by the Commonwealth Government. There has been a very welcome absence of complaints from overseas regarding breakages, falling off in quality, and defects in packing, which were, unfortunately, associated with former years, and, generally speaking, exporters have expressed satisfaction with prices realised. Breakages were less than half of 1 per cent.

SEASON'S EXPORTS.

The record quantity of 5,895,090 dozen eggs were exported during the season, the various States contributing the following quotas:—

| | |
|-------------------------|-------------------------|
| New South Wales | 2,434,020 dozens |
| Victoria | 1,612,080 " |
| Queensland | 831,210 " |
| South Australia | 673,560 " |
| Western Australia | 344,220 " |
| Total | 5,895,090 dozens |

The following table shows how Australian exports have steadily increased since 1927:—

| | N.S.W. doz. | Vic. doz. | Q'ld. doz. | S.A. doz. | W.A. doz. | Total. doz. |
|------------|----------------|--------------|---------------|--------------|--------------|----------------|
| 1925 | 802,421 | 393,142 | 30,151 | 266,730 | 39,300 | 1,531,744 |
| 1926 | 1,839,046 | 616,561 | 191,458 | 318,900 | 186,025 | 3,151,990 |
| 1927 | 447,996 | 343,020 | 236,484 | 11,250 | 65,255 | 1,104,005 |
| 1928 | 858,798 | 727,952 | 824,704 | 393,250 | 111,634 | 2,916,338 |
| 1929 | 1,627,780 | 472,200 | 919,410 | 358,490 | 174,720 | 3,562,580 |
| 1930 | 2,434,020 | 1,612,080 | 831,210 | 673,560 | 344,220 | 5,895,090 |

It will be seen from the above that—

| | | |
|--------------------------|---------------------------------|-----------------------------------|
| N.S.W. has risen from | 447,000doz. in 1927 to | 2,434,000doz. in 1930 |
| Vic. " | 343,000doz. " | 1,612,000doz. " |
| Q'ld " | 236,000doz. " | 831,000doz. " |
| S.A. " | 11,000doz. " | 673,000doz. " |
| W.A. " | 65,000doz. " | 344,000doz. " |

The demand for eggs is steadily growing in Great Britain, and the following table gives an interesting comparison for the years 1928 and 1930:—

| | 1928. | 1930. |
|----------------------------------|------------------------|------------------------|
| Home production of Eggs | 199,663,333doz. | 211,666,660doz. |
| Imports into Great Britain | 264,670,000doz. | 285,609,140doz. |
| Total Consumption..... | 464,333,333doz. | 477,275,800doz. |

The steps which Great Britain took in 1928 to foster her home production have been rewarded by the production of an additional 12,000,000 dozen eggs per annum, but despite this fact, it is gratifying to learn that, whereas in 1928 Australia supplied only three eggs out of every 1,000 consumed in Great Britain, she now supplies 12 eggs in every 1,000 consumed.

Consumption of eggs has been greatly stimulated in Great Britain, and it is estimated that 26,500,000 more dozens of eggs were consumed than during the preceding year. In fact, production in England during 1930 was the greatest ever known. Another important factor which helped to make a market for imported eggs was that Russian eggs, which usually have an important bearing on the market, were not handled to any extent during the season.

The preceding table shows the prices received during the 1930 Australian export season, and a comparison is appended showing the prices received for South African and Argentine eggs during the same season when Australian eggs met the direct competition of countries of the Southern Hemisphere having the same season of production. Two interesting points revealed in this table are, firstly, the drop in prices which took place about the Christmas season, and although not so definitely marked in the 1930 season, it has occurred in every season. As a matter of fact, in a cablegram received from the High Commissioner on the 27th January it was stated that eggs of the 15lb. pack were then realising 10s. 6d. per long hundred. This, as against 16s. 3d. on the 7th November and 15s. on the 19th December.

The other point to be noticed is that South African eggs fetched a higher price than Australian eggs week by week.

SOUTH AFRICAN COMPETITION.

Although it is known that South African eggs must necessarily be fresher than Australian on account of the differences in distance of the two countries from England, it is not considered that this is the dominant factor in such price discrimination. South Africa has, in recent years, conducted an intensive publicity campaign in England, and last year went so far as to send a publicity representative to England for the sole purpose of placing South African eggs prominently before English consumers. This representative had nothing whatever to do with sales, but concentrated on publicity. Large displays were made on railway stations, hoardings, exhibitions in large stores and stands arranged at trade exhibitions, and advertisements in newspapers, in all costing £1,200, and South African exporters would seem to have been fully repaid by the enhanced prices received. (The funds for this campaign were raised by a small levy on exports.)

A further reason for the South African price advantage last season may be found in the fact that the minimum of her 15lb. pack (which is the most popular pack) is 1½ozs., whereas the minimum of the Australian 15lb. pack was 1¼ozs. The Australian pack looks irregular and compares unfavorably alongside the South African pack, with which it is sold in competition.

The following table shows the quantity of eggs of each pack which were exported by the various Australian States during the season:—

Cases of 30 Dozen.

| | 12lb. | 13½lb. | 14lb. | 15lb. | 16lb. | 17lb. | 18lb. | Duck. | Total. |
|----------------|-------|--------|--------|---------|--------|-------|-------|-------|---------|
| N.S.W. | — | — | 37,004 | 14,257 | 30,373 | — | — | — | 81,634 |
| Victoria | 500 | 366 | 176 | 47,983 | 1,937 | 2,724 | 61 | 353 | 54,100 |
| Queensland .. | — | — | — | 27,686 | — | — | — | — | 27,686 |
| Sth. Australia | — | — | 101 | 23,505 | 86 | 1,500 | — | — | 25,192 |
| W. Australia | — | 952 | 512 | 8,719 | 1,161 | 130 | — | — | 11,474 |
| Tasmania .. | — | — | — | — | — | — | — | — | — |
| Total .. | 500 | 1,318 | 37,793 | 122,150 | 33,557 | 4,354 | 61 | 353 | 199,986 |

The proportionate make-up of the different packs in the total export during the season was as follows:—

| | % |
|-------------------|-----|
| 13½lb. pack | 0.6 |
| 14lb. pack | 19 |
| 15lb. pack | 61 |
| 16lb. pack | 17 |
| 17lb. pack | 2.4 |

It will be seen that the 15lb. pack was still the popular pack in all States, although it will be remembered last year its minimum was reduced to 1¼ozs. in place of the 1½ozs. of the previous year. In New South Wales, however, 37,004 cases of the 14lb. pack were exported and 30,373 cases of the 16lb. pack, but only 14,257 boxes of the 15lb. pack.

THE 13½LB. PACK.

Attention is drawn to the very small percentage of the 13½lb. pack exported, although the regulations were specially amended at the insistent demand of exporting interests to permit such a pack being exported in the 1930 season. The opinion is expressed that too many varieties of lower grade eggs are not helpful to marketing conditions, as they all serve to fill the same price retail. The results show that the amendment of the regulations to permit a pack of 100 per cent. 1½oz. eggs being exported was not justified, and as the amendment was granted subject to review at the end of the season, consideration will be given to the exclusion of this pack in future shipments. During the year certain criticism was levelled at the Department for allowing so many packs for export, and a proposal was made that the English standards for grading should be adopted. The following statement, which was issued by the Department, on the proposal sets out the case for the grading standards adopted, and is thought worthy of repetition here:—

“The fact must not be lost sight of that we do not sell our eggs in competition with English eggs. The English egg is a fresh egg; the Australian egg must always be from six to eight weeks older, and the fact that the word ‘Australia’ is stamped on its shell in accordance with English requirements makes this fact always apparent. The English buyers of Australian eggs, therefore, look for good quality, good packing ensuring minimum breakage, and uniformity in size. It goes without saying that the first two factors are the primary conditions of sale, and apart from the state of the market at any given time, uniformity in size must be the final determinant of the price realised.

“If a buyer finds in the eggs offered a wide variation in size, his offer will invariably be based on the size of the smallest sized egg in the pack. Therefore, by providing minimum and maximum weights for the eggs in any particular pack, it follows that every pack is of uniform size and the price must be based accordingly. The English regulations provide for four grades, viz.:—

Pullet eggs, which are under 1½oz.

Medium eggs, which must be of 1½oz. minimum.

Standard eggs, which must be of 2oz. minimum.

Special eggs, which must be of 2½oz. minimum.

“But the point to be noted is that no maximum is provided under any grade, except pullet eggs, and these are prohibited from export from the Commonwealth.

“The Commonwealth regulations at present in force provide for six grades:—

No. 1. 13½lb. to the long hundred (10doz.) of 1½oz. eggs.

No. 2. 14lb. to the long hundred (10doz.) of 1½oz. to 2oz. eggs.

No. 3. 15lb. to the long hundred (10doz.) of 1½oz. to 2½oz. eggs.

No. 4. 16lb. to the long hundred (10doz.) of 2oz. to 2½oz. eggs.

No. 5. 17lb. to the long hundred (10doz.) of 2½oz. to 2¾oz. eggs.

No. 6. 18lb. to the long hundred (10doz.) of 2¾oz. to 3oz. eggs.

“If a study of these regulations be made it will be seen that there are three grades, namely, the 13½lb. pack, the 14lb. pack, and the 15lb. pack, in which exporters may pack to conform to the requirements of the English medium egg; that the Australian 16lb., 17lb., and 18lb. packs conform to the requirements of the English standard egg; and that the 18lb. pack provides the equivalent of the English special egg. Should, however, the English standard be adopted, the whole of the export surplus would be put up as the 1½oz. minimum pack, and eggs ranging from 1½oz. to 2½oz. would be indiscriminately mixed, no uniformity would be observed, the objects of grading would be defeated, and buyers would base their price on the smallest sized egg in the pack, namely, the 1½oz. egg. For this reason, therefore, the Department of Markets has at all times placed before the egg industry the desirability in its own interests of maintaining close grading, and only consented to the special provision for 1½oz. eggs for this season to prevent a glut on the local markets with which the industry as a whole represented itself to have been faced.”

EXPORT OF OILED EGGS.

During the season approval was given to the exportation of eggs which had been subjected to a process of oiling for the purpose of checking evaporation. When these eggs arrived in England it was ascertained that the regulations of the Ministry of Agriculture and Fisheries prescribed that eggs so processed must be marked on the shell with the word "preserved." On outturn it was found that the quality of the eggs so processed was excellent, but an abnormal percentage was broken throughout all the consignments.

The effect of the words "preserved" was to reduce the value of the eggs from 2s. to 3s. per long hundred below average market price for the same eggs unstamped. Thus the object of the oiling to prevent evaporation was defeated by the regulation which provides that eggs so treated must be marked "preserved." In fact, as one importer stated, although the eggs are equal to, and perhaps better than, eggs which had not been oiled, the fact remains that when an English buyer buys eggs which are stamped "preserved," he expects to get them at a discount.

Furthermore, a careful investigation was made as to why oiled eggs should be more susceptible to breakage than eggs which had not been oiled, and it is the considered opinion of representative English importers that the oiling process creates a surface on the shell that has a definite resistance to the filler, the result is that eggs stand suspended in the filler, and when other layers are super-imposed, plus the extra pressure of the lids and the wiring, the eggs are crushed. In addition to this, oiling gives a hard and unnatural appearance to the shell; it also creates a certain amount of brittleness in the shell, as when the pores of the eggs are sealed the shell does not possess the same resiliency, and consequently breaks more easily.

BRANDING.

Some exporters sent eggs to England during the season with only the top and bottom layers branded, the eggs in the middle layers being unmarked. These were criticised by the Customs authorities, who took a very serious view of the matter. It is remembered that an unbranded egg in England is treated as an English one, and has a much greater value than the imported egg at the time when Australian imports are arriving on the market. Exporters are warned against this practice as the Customs authorities have notified that they will take drastic steps in the future if instances be discovered. The need is stressed of protecting the Australian reputation in this regard.

It is also pointed out that the stamping of the word "Australia" was, in too many instances, a mere indecipherable smudge. Apart from the requirements of the English Merchandise Marks Act not being fulfilled, the consumers' objection to such an egg when placed before him will be easily understood, and above everything else it is a bad advertisement for the Australian product.

CASES NOT NAILED.

Another complaint was that some cases arrived which had been wired, but not nailed. When these cases were opened in an inverted position, breakages were considerable. The attention of the trade is drawn to this complaint, and it should be easily rectified by nailing the lids. On this score also a misapprehension arose regarding the labels, which were considered to be put on upside-down.

WASHED EGGS.

An experimental shipment of washed eggs was made during the season. The eggs arrived in England in a state of putrefaction, the yolks having been dissolved in the whites. It would appear that washing increases the porosity of the shell, and thus permits a higher rate of evaporation, because the protective film on the shell is destroyed.

The department will, therefore, not permit the export of washed eggs in the future, and it is pointed out that if proper care is exercised on the farm there should be no need for eggs to require washing.

Evidence Ford Quality

Australia's greatest City Councils choose Ford Vehicles!

TO meet the strict requirements of City Council work, motor vehicles must measure up to high standards of quality, dependability, performance and economy. Significant, then, that after years of experience with many makes, the Melbourne City Council has standardised on Ford Cars, Trucks and Light Deliveries for all vehicles of up to two tons capacity, while the Sydney Municipal Council has a fleet of no less than 120 Ford vehicles.

And these City Council fleets must be British. Throughout Australia there is a demand that public money be invested in British products. Authentic figures prove the Ford British content unusually high even among English makes, some Ford models ranging up to 92% British in actual manufacture.

The Ford commercial range covers thirty distinct standard models from half ton to two tons capacity . . . And special equipment is available which increases the Ford Truck's capacity to four tons, yet with running costs increased only 15 to 20% over those of the standard 30 cwt. Truck. Extended chassis, six-wheel equipment, trailers and semi-trailers can be supplied through your nearest Ford Dealer. Ask him for facts and figures of Ford transportation costs. These will assure you of Value far above the Price.

Sydney Municipal Council uses these Ford Cars and Light Delivery vehicles in its Electricity Department

SHIPMENTS TO OUTPORTS.

Shipments to ports other than London were considerable during the season, with the result that the reputation for Australian eggs is extending beyond the English metropolis, and the severe losses through breakage on the English railways, when eggs were extensively transported from London to such cities as Liverpool, Hull, and Glasgow, are being avoided.

The following comments are, however, made respecting the outports:—

Liverpool is the best west coast centre for consignments, as the port possesses the best facilities for handling, and is also the most convenient for re-transportation to the Midlands and the adjacent areas. Furthermore, ample cold storage accommodation is available there in case of need.

Hull.—Buyers showed a disinclination to taking delivery from this port in the early part of the season. There is a good deal of trade depression in this area, and "cheap" eggs were the only ones in appreciable demand. Furthermore, many merchants in the area have running contracts for Danish pickled eggs. During the latter part of the season Manchester buyers were induced to take delivery ex Hull, and the prospects for a continuance of this plan next season are promising, although the fact must not be overlooked that this means transport by rail with consequent risk of breakage.

Glasgow.—This port has excellent prospects, but great difficulty is experienced by Australian shippers in securing direct freight to this port, and even when it is secured there is always the risk that a steamer will take a very long time to reach Glasgow on account of the many intermediate European ports called at.

It was noted that small eggs sold readily and at fair competitive prices in Liverpool and Manchester, but, if possible, such eggs should not be sent to Glasgow or London. In both these cities the principal importers are nervous lest these small eggs should be associated in the mind of the trade with Polish, Egyptian, and Chinese eggs of poor quality.

MARKETING OF AUSTRALIAN EGGS.

In summing up the lessons to be learned from the 1930 season, there is one outstanding feature which exporters would be strongly advised to bear in mind, and it is the fact that all Australian eggs should be shipped in time to reach the market before the English Christmas season. All exports landed after that time meet a rapidly falling market. Furthermore, Australian exporters are warned that observation shows that the home producers have greatly improved their methods under the encouraging stimulus given them by the Hume Government, and are concentrating their endeavors to bring about the earlier production of new laid eggs by a week or even more, so as to catch the Christmas markets. If this is accomplished, Australian exporters will have to make such arrangements as to ensure the clearing of all stocks before the arrival of English and Continental new laid stocks on the English market.

ADVERTISING.

The proposal that the egg exporting industry participate in the Australian trade publicity campaign in Great Britain has been adopted by the interstate conference of egg producing exporting interests, which met in Melbourne recently. The conference recommended that a levy of 2d. per case be made on all exports for the purpose of raising the necessary funds for advertising.

CANADIAN MARKETING POSSIBILITIES.

One of the features in past years has been the reluctance of exporters to cease export operations to Great Britain early in November, as the consequent flooding of Australian markets with eggs diverted from export naturally caused a fall in local markets. It is in this connection that the Canadian Market offers possibilities, and if Australian exporters would co-operate in November and December to secure space on eastern seaboard American steamers and exploit the Canadian Market, it is possible that local markets could be kept on an even keel and another market opened up abroad.

The details of the prospects of the Canadian marketing scheme may be gleaned from the following:—

“Some years ago there was a large spread in Canada as between winter and summer prices. There has, however, in recent years, been a sustained campaign for the encouragement of winter egg production, which seems to have brought about results, particularly in British Columbia, consequently the spread is not now what it used to be, and one indication of this is to be found in the Canadian storage arrangements. The practice of cold storage owners is to quote merchants a flat rate per case for storage for the entire season, the holder being free to quit his stocks at any time. About ten years ago, the rate covered a period from the time of intake (April-June) up to the 15th of January following, but later the period was reduced to the 1st of January, and about two years ago was altered to the 1st of December. Increased storage charges accrued after that date. Accordingly the storers generally plan to quit stocks gradually between September and the 30th November, unless exceptional market conditions justify a longer carry over. Montreal commenced trading on April-June, 1930, cold stored eggs at the end of August last.

“Apart from the tendency for local winter production to increase (particularly in British Columbia, where the winter is milder), the practice has been to import from the United States as from December, and the fact that United States supplies are usually available then, has been a factor influencing the December 1st storage date arrangement. The Canadian import duty against the United States is 10 cents per dozen, whilst Australian eggs are admitted free into Canada at present under our treaty. Australian exporters have, therefore, an advantage of 10 cents per dozen over the U.S.A. product.”

Thus the diversion of the Australian product from the United Kingdom to the Canadian market, at the moment when it is desirable to cease exporting to United Kingdom, would seem to be well worthy of consideration.

Concerning the possibilities of marketing Australian egg pulp in Canada, it is realised that the present duty of 10 cents per lb. is a big handicap; but it is the intention of the Australian Trade Commissioner in Canada to take the matter up with the Canadian Government, with the view of having Australian egg pulp admitted into Canada free of duty, as are Australian eggs admitted free under the Australian Treaty. The best packs recommended for Canadian trade are the 15lb. and 16lb. packs.

OTHER CONSIDERATIONS.

Other matters for consideration may be briefly set forth as follows:—

- (1) A mixing of brown and white eggs seems to be desired by English exporters.
- (2) The legible stamping of the word “Australia” on all eggs.
- (3) The stamping of all eggs in each case, not the top layers only, as the English authorities regard this as a very serious breach of the Merchandise Marks Act.
- (4) The need for egg exporting interests throughout the States to co-operate to ensure regular weekly shipments. South Africa was able to arrange regular weekly supplies on the London market, and although the difficulties confronting Australian exporters in this respect are known, still the Department considers that this aspect of the trade can be improved.

It is undesirable that Australian eggs be landed in large quantities in one week on the English market and a fortnight later to find the market bare of supplies.

It is considered that the steps that have been taken in forming a provisional Commonwealth Council of State Egg Producers' Organisations are very desirable in the interests of the industry to co-ordinate efforts and deal with export problems, pending the creation of Egg-marketing Boards in each State, from which might be created a Commonwealth Board for the control and disposal of eggs and egg pulp.

RATIONS FOR DAIRY COWS.

Special interest has been shown by many producers in this State in the remarks made by Mr. F. Coleman (Chairman of the Advisory Board of Agriculture) at the Lyndoch Conference, and reported in the March issue of this *Journal*. Mr. Coleman has received numerous inquiries with reference to the meal included in the balanced rations which were drawn up after consultation with Mr. H. B. Barlow (Chief Dairy Instructor). For cows producing 3galls. or 4galls. of milk the rations were calculated on the use of linseed meal (Meggett's), and the table of balanced rations was as follows:—

For a 3gall. cow—

| | | |
|-------------------|--------|---|
| Wheaten hay chaff | 20lbs. | Ratio albuminoids to carbohydrates, 1-5.2 |
| Wheaten bran | 4lbs. | |
| Linseed meal | 2lbs. | |

or

| | | |
|-----------------|--------|-------------|
| Oaten hay chaff | 20lbs. | ratio 1-5.0 |
| Crushed oats | 4lbs. | |
| Linseed meal | 2lbs. | |

For a 4gall. cow—

| | | |
|-------------------|--------|-------------|
| Wheaten hay chaff | 20lbs. | ratio 1-5.9 |
| Crushed oats | 4lbs. | |
| Wheaten bran | 4lbs. | |
| Linseed meal | 2lbs. | |

For a 3-4gall. cow—

| | | |
|-----------------|--------|-------------|
| Oaten hay chaff | 20lbs. | ratio 1-5.2 |
| Wheaten bran | 4lbs. | |
| Crushed oats | 4lbs. | |

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF YORKE PENINSULA BRANCHES.

The Annual Conference of Branches of the Agricultural Bureau was held at Maitland on April 15th. There was a good attendance of delegates from the following Branches:—Weavers, Moonta, South Kilkerran, Boor's Plains, Wauraltee, Yorketown, Petersville, Kilkerran, Paskeville, and Brentwood, in addition to visitors from Kadina, Minlaton, and Maitland.

The Department of Agriculture was represented by Hon. S. R. Whitford, M.L.C. (Minister of Agriculture), Mr. F. Coleman (Chairman Advisory Board of Agriculture), Professor A. J. Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), R. H. F. MacIndoe, B.V.Sc., M.R.C.V.S. (Deputy Chief Inspector of Stock), R. Hill (District Agricultural Instructor), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau). Messrs. E. Giles and B. Pattison, M'sP. for the district, were also present.

Mr. J. J. Hentschke (Chairman of the Artherton Branch) presided and extended a cordial welcome to officers of the Department and delegates from district Branches. Mr. C. H. King (Mayor of Maitland) extended a civic welcome to the visitors.

The opening address was delivered by Hon. S. R. Whitford, M.L.C. (Minister of Agriculture). At the instance of Mr. E. Giles, M.P. (Weavers), seconded by Mr. B. Pattison, M.P., a vote of thanks was accorded the Minister for his attendance and opening address.

During the course of the Conference the following papers were read and discussed:—"Dairying," Mr. G. T. Hicks (Artherton); "Profitable Farming on Small Holdings," Mr. B. P. Dutschke (Kilkerran); "Best Type of Horse to Breed, Suitable for General Farm Work," Mr. T. Bodda (Boor's Plains); "Winter and Summer Fallowing," Mr. S. G. Chynoweth (Boor's Plains); "Economy on the Farm," Mr. R. Burns (Artherton); "Tractors," Mr. W. Heinrich (South Kilkerran); "Milk Fever," Mr. L. Moar (Paskeville). A large number of questions were included on the Agenda, and these were replied to by Officers of the Department.

Conference carried the following resolutions:—1. "That the 1932 Conference be held at Kadina, with arrangements in the hands of the Boor's Plains Branch." 2. "That this Conference protests against the high charge for handling wool at Port Adelaide by the wool brokers." 3. "That this Conference strongly protests against the high charges for wharfage and haulage at Peninsula ports." 4. "That this Conference suggests that, in view of the difficulty which the farmer has in obtaining authentic information regarding the world's production of his products, we suggest that the Agricultural Bureau establishes, in conjunction with other countries, if possible, an international bulletin to be published every three months."

On behalf of the Northern Yorke Peninsula Field Trial and Show Society, Mr. J. P. Pontifex, Chairman of the Society, presented the following trophies to successful competitors in the Northern Yorke Peninsula Crop Competition:—First prize, H. E. Aldenhoven (Artherton), silver shield; first prize, Artherton Branch Competition, O. D. Jericho, silver cup; first prize, Paskeville Branch Competition, G. Meier, silver cup; first prize, Boor's Plains Competition, A. Adams; second prize, S. G. Chynoweth, silver cup.

METTER'S "NUOIL" DOUBLE GEARED SELF-OILING WINDMILLS.

IN SIZES FROM 6ft. TO 14ft. WHEEL.

The strongest, best lubricated, best designed, and best governed.
Pump more water on a lighter breeze.

No spring on automatic oiling system to break, and no sheet-metal
oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923,
1924, 1925, 1928, and 1930 (no entry 1926-29).

Also Gold Medal at the All-Australian Exhibition, 1930.

A reliable and useful investment, and the popular choice of experi-
enced pastoralists, farmers, and others.

METTER'S 5ft. "MINOR" WINDMILLS.

Most efficient for pumping water from shallow
depths.

MILL ONLY, £9 15/0; on 15ft. G.I. TOWER,
£15 15/0; on 20ft. TOWER, £17 17/6.

METTER'S FUEL STOVES and WASHING COPPERS.

Use less fuel and retain heat longer.

WHOLLY MANUFACTURED IN SOUTH
AUSTRALIA BY

METTERS LIMITED,

98, 99, 100, North Terrace,
ADELAIDE.

"NO FEAR OF A DROUGHT WITH A
METTERS ABOUT."

GOLDSBROUGH, MORT & COMPANY LTD.,

STOCK AND STATION AGENTS,

**WOOL AND PRODUCE BROKERS, SHIPPING AGENTS, GENERAL IMPORTERS AND
EXPORTERS, LAND, LOAN, FINANCIAL, AND INSURANCE AGENTS.**

— **GENERAL AGENTS IN AUSTRALIA FOR WESTERN ASSURANCE COMPANY.** —

For any information regarding Fat, Store, or Stud Stock, communicate with our Stock Depart-
ment for expert attention.

Distributing Agents in S.A. for—

"EDWARDS'" SHEEP DIPPING POWDER

"TONK'S" RABBIT TRAPS

"NATIONAL" CEMENT (in bags)

"RUSSELL'S" PIPING.

"COMET" WINDMILLS

"KING-LOC" STEEL DROPPERS

"W.M.L." and "TOP" BRANDS SUPERPHOSPHATES and MANURES

All Farm and Station Requirements, Fencing Wires and Standards, Cornsacks, Twine, Oils,
etc., "Tattoo" Sheep Branding Oil.

"CLAN LINE AND SCOTTISH SHIRE LINE STEAMERS."

Sub-agents for—

**ORIENT LINE STEAMERS, AND AUSTRALIAN AERIAL
SERVICES, LIMITED.**

Main Office in South Australia: 18, KING WILLIAM STREET, ADELAIDE.

Head Office: MELBOURNE.

[The following papers were read by members of Yorke Peninsula Branches of the Agricultural Bureau at Maitland on April 15th.]

DAIRYING.

[G. T. HICKS, Arthurton.]

Owing to the recent slump in grain prices we naturally turn to other branches of farming in an endeavor to obtain sufficient money to enable us to purchase necessities, and also to assist in paying accounts which cannot be met with the proceeds from grain. Two very profitable sidelines are cows and pigs, which, in my opinion, should be considered conjointly, because in this district we have to rely on butterfat as the main source of revenue from cows, whilst skimmed milk can be fed very profitably to pigs.

Previously, especially in these districts, high prices, and in some cases high yields, encouraged us to neglect sidelines which were considered a tie, and also as being unprofitable because a fair quantity of grain and hay was required, which at that time was expensive. The decrease in value of these sidelines and their products has not been so marked as has been the case with grain. But even with the high price of grain, we would have been amply repaid for feeding some grain to stock and marketing it in the shape of butter, pigs, and calves, or cattle. In this way an export market for dairy products may have been started. Now, this branch of the export trade is practically negligible; in fact, during the lean periods of the year South Australia imports a considerable quantity of butter from other States. Had these branches of revenue been fully exploited, there would be little trouble in allowing grain to remain low, if it ceased to be profitable.

THE BUILDINGS.

When handling cows a milking shed and dairy is necessary. The site for the milking shed should be well drained, or attempts made at artificial drainage. For farm use, a wood and iron shed will meet requirements. The Dairying Regulations recommend brick or concrete floors which can be washed daily. Should the regulations be made so as to enforce this being done, it would fall rather hard on some who are not fortunate enough to have a water tap at the shed. However, such a procedure is advisable, as milk is one of the quickest germ collectors in existence. If dairying is to be practised extensively, a stone, brick, or concrete building would be more suitable than iron. The milking shed should not be close to stables or pigsties. A cool room is advisable for storage of milk, butter, and cream, and also as a separating room.

THE HEAD OF THE HERD.

As soon as sufficient good cows are in hand, a good bull should be purchased, or the services of a good bull obtained. The Government Subsidy Scheme gives encouragement to people to purchase good stud bulls from tested and selected cows by paying one-half of the purchase price to the buyer, two-thirds of which is paid on purchase and one-third at the end of two years, e.g., a bull may cost £30; £15 equals half, £10 is paid on purchase and £5 at the end of two years. This applies to bulls whose value does not exceed £50 and age not less than 10 months. If stud bulls were always used, a far better class of dairy cow would be for sale and in use than is the case to-day, and production would be much higher. I say this because stud breeders are always culling low producers and animals showing faulty bodies or udders. This is not so with "scrub" bulls, which in most cases are a mixture of breeds, and are only used as a means of getting a cow in calf. Some attempt should always be made to have pure-bred animals, and if crossing is adopted, go no further than the first cross. A man may cross a Jersey and Shorthorn. If this is a heifer, use either a Jersey or Shorthorn bull on her. In any case never use a crossbred bull.

THE JERSEY.

I prefer the Jersey. She is small in body and consequently does not require such a large amount of feed for body maintenance as a larger animal. Also, if she is given more food than is necessary, she is more likely to give an increase in production than lay on fat, which is the tendency with the heavier breeds. The strong points with Jerseys are quality and economy of production, but occasionally very heavy milkers are obtained. For the last five years Jerseys have proved superior to all other breeds in herd tests in South Australia, New South Wales, and Victoria. By this I do not mean to say that Jerseys have topped the list in all classes in single tests. Taking the herds right through, Jerseys have averaged higher butterfat than other breeds. Heavy breeds give a few outstanding cows, but there are more of the low producing class in these than there are with the Jersey. In these tests no record is kept of feeding, but had such been done, the Jersey would again have added to her honors. A point often raised is that Jersey calves and cattle do not realise such high prices in the saleyards as heavy breeds. This is quite so, but when economy of production and extra production is taken into consideration, the Jersey will again be the winner. Jerseys can be brought into profit much earlier than heavy breeds and their period of production is much longer.

Cows should be milked regularly, and under no circumstances be left overnight without milking. They should be properly fed and not expected to do their best on pasture alone. A point often raised is that this country is not suitable for dairying, but if one has a good water supply, good chaff, a supply of ensilage and a lucerne patch, cows can be made to produce as well here as in any other part of the State. Of course, these commodities are not all that is required to feed a cow. In addition, bran, crushed oats, and linseed meal are advisable. Also a good cattle lick is advisable, or else some phosphatic material given in the feed. A pamphlet entitled "Feeding for Production," issued by the Department of Agriculture at the price of postage, gives valuable information on feeding dairy cattle. Calves should never be allowed to get too fat, unless intended for market purposes.

PIGS.

A good, well-drained site should be selected for pigsties. Small sties are required for fattening and breeding purposes. Decide whether to breed or fatten and concentrate on one line. If a person can attend to breeding and fattening at the same time, it is much better, because he can obtain the right kind of pig without having to rely on markets for his supplies. The *Journal of Agriculture* for March, 1931, gives an interesting article on recent experiments held at Roseworthy Agricultural College to determine the most suitable breed for curing purposes. In these tests, the Large White was used for practically all crosses. The Large White is at present considered the best for all purposes in England. In the recent experiments the Large York x Mid York carcass was considered the best.

Financial returns per pig ranged between 12s. and 16s. The Large White x Gloucester Old Spot gave the highest return, but worst carcass, also most waste in preparation for curing. The Tamworth x Berkshire gave a perfect carcass. Pigs with dark skin gave the best scald. With a dark-skinned animal there is not the tendency to go red that there is with white pigs. Tamworth x Berkshire showed smallest loss in slaughtering and Large White x Mid York highest. In six lots, the variation was between 22lbs. and 26lbs. Large White x Gloucester Old Spot was the most economical pig to feed, also the fastest maturing, taking 19 weeks, whereas Large White (Pure) took longest, 22½ weeks. Cost of food per pound weight increase ranged between 2.04d. per lb. and 1.58d. Maturing weight was 160lbs. live weight.

The ration supplied was:—Wheat 5 parts, barley 2 parts, peas 1 part. For the morning feed the above mixture was fed with skim milk 4lbs. per pig. In the evening the same ration was given with half-part meat meal. All grains were crushed and mixed with meat meal and mineral mixture and fed dry. Mineral mixture was fed

at rate of 1 per cent. of grain mixture. Ingredients of mineral mixture were:—Superphosphate or ground rock phosphate 40 per cent., salt 20 per cent., charcoal 20 per cent., Epsom salts 5 per cent., sulphate of iron 5 per cent., sulphur 5 per cent., bicarbonate of soda 5 per cent., potassium iodine $\frac{1}{2}$ per cent. Drinking water was always supplied. As much dry feed as pigs would eat was given. Lucerne was fed at the rate of 1½ lbs. per pig per day. Pigs should always be supplied with some material for bedding, and on no account forced to wallow in mud in winter. If a pig likes mud to roll in allow him to have it, but there is no reason why the sties should be a mudhole in which the animals are compelled to remain. Good sheds are required for shelter. When breeding, a sty for farrowing purposes should be provided with a rail so that young pigs may get behind it and not be squashed. This is not always necessary, but is at all times a safeguard. Sows when farrowing should not have long straw, but broken straw or sawdust. When feeding sows, plenty of good milk-forming materials are required. On no account allow a sow, especially a sow with her first litter, to become too fat.

Mr. C. B. Stead (Yorketown), speaking on the question of pig feeding, asked the writer if he favored keeping a supply of food continually in front of pigs. Mr. Hicks' advice was to use a self-feeder, fill it with crushed grain, and allow the pigs to feed at will. In the case of feeding milk, only sufficient that could be eaten at one meal should be fed. Mr. J. J. Honner (Brentwood) expressed the opinion that so far as Yorke Peninsula was concerned dairying should only be undertaken for the requirements of the farm. Mr. L. Slade (Weavers) said the cost of freight from the southern end of the Peninsula to the Adelaide market was so high that it dissipated any profit that there might be in pig raising. He also mentioned the rather rapid change from the once very popular Berkshire x Tamworth Cross to the Large White so much favored at present.

Discussing this aspect of the pig industry, Mr. W. J. Spafford (Deputy Director of Agriculture) said at the present time the Large White was the most important breed of pig in the world. It was the main breed from which the bulk of the £63,000,000 worth of pig products imported in Great Britain each year was derived. Of this huge amount of money £40,000,000 worth was obtained from foreign countries, and if Australia wished to partake in this, they would have to adopt the White Pig.

It was the breed from which the Wiltshire sides of bacon were obtained. The Large White was fulfilling the requirements of the overseas market, and we in Australia, with our very considerable disadvantage of distance from markets, must realise that to share in the trade we must meet the demands of the purchaser and also send pigs of first-grade quality. The principal drawback of White Pigs in this country is their tendency to scald in the hot sun. If, however, the young pigs were allowed to run in the open all the year round, there would be very little danger of scald.

FALLOWING.

[S. CHYNOWETH, Boor's Plains.]

In the wheat belt the summer is practically rainless and the wet season does not begin until about April. The crop is sown between May and June and fallowing begins soon after. Thus, at least three months' wet weather normally occurs before fallowing begins, and four and possibly five months before it is finished. At first, all the rain soaks into parched soil, but sooner or later, especially during heavy falls, the soil cannot take it up fast enough. A good deal runs off the paddocks, and some lies about in shallow pools and evaporates. When the plough is started in July, one has started early enough for first class winter fallow, but even then it is not possible to trap the rain which has run off or evaporated during the three preceding months. That can only be done by summer fallow. Not only does summer fallow catch the early rains, but it is advantageous from several other points of view.

SUMMER FALLOW.

The land is opened up in February, March, or April, and lies bare for 14 or 15 months before it is sown. This method, however, cannot be employed regularly on those soils which cannot be broken up in the absence of rain; but, on the other hand, there are extensive areas which are more easily broken up dry than when wet. On very loose soils it is sufficient, in the first operation, to merely stir the soil 2½ ins. deep with a spring-toothed cultivator, but, if necessary, the plough scarifier, or a one-way cultivator, will do satisfactory work. If the soil breaks up rough, it is desirable to harrow it and then it may be left until after drilling. The early tillage promotes a profuse germination of rubbish when the first rain comes. Sheep should be given access to the paddock, but once weeds get too far ahead, it will be necessary to get rid of them by cultivation. At this stage, generally, a scarifier will be equal to cutting weeds, and at the same time stirring the soil to a depth of about 2 in. or 3 in., but if a light implement is used for the first operation, a plough may have to be used for the second working. Later, as rubbish appears, it must be killed by using the lightest implement that will do the job satisfactorily. As spring advances, the aim should be to create a well-defined mulch of loose, meadow soil about 2 in. deep, overlying a firmly consolidated seedbed. On soils which have a tendency to run together, the mulch should be left comparatively cloddy, but on good loamy soils it can be fairly fine. The effect of the mulch is to reduce to a minimum the evaporation of moisture previously stored in the soil. As summer advances, an occasional "sheeping" of the fallow will suffice to prevent any oats from seeding, but should half an inch of rain fall, it will generally pay to give a quick harrowing to break any crust that may have formed on the surface. It is very important to recognise that a crusted surface is one through which moisture evaporates at a faster rate than through a loose surface. By permitting the crust to remain, the whole of the moisture previously stored may be lost.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1931—

Eggs for Hatching and Day old Chickens**WHITE LEGHORNS.**

EGGS.—10/- per setting of 15 Eggs. Incubator lots £2 per 100.

DAY OLD CHICKENS.—15/- per dozen. £5 per 100.

BLACK MINORCAS.

EGGS.—12/6 per setting of 15 Eggs. Incubator lots £2 10s. per 100.

DAY OLD CHICKENS.—17/6 per dozen, £6 per 100.

Free on Rail, Salisbury. DELIVERY, July, August, and September.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Victoria Square, Adelaide.

C. F. ANDERSON, Poultry Expert.

In the following autumn, after the weather breaks, the land can be worked up, and then, after allowing sufficient time for weeds to germinate, sown with a combined drill. Further, the germination of wheat is stimulated. There is nothing better for the promotion of a good sprout of rubbish on a paddock than to summer fallow it. Thus, the system can be employed to clean up the dirtiest paddocks on the farm. When a paddock which it is intended to fallow is particularly foul with weeds, it is sometimes found desirable to restrict the first operation to a light cultivation. In this way, the seeds are not buried deeply to become a menace in later years. They sprout immediately and may be destroyed.

As a word of warning to the man who is summer fallowing a dirty paddock for the first time, I would say, do not do it unless you can cope early with the growth promoted, otherwise the paddock may have to be reploughed, and at the best an unsatisfactory result obtained. Rather than attempt to summer fallow all the land it is intended to crop, it will be most economical to treat half in that way and winter fallow the rest, thus the available labor on the farm can be most economically distributed. Some of the heavy work can be undertaken in February and March, when the teams would otherwise be idle, and the balance can be left until after seeding. The practical advantages in respect to weed killing and distribution of labor should stamp the practice as worthy of adoption wherever it can be employed.

WINTER FALLOW.

The time has come when the farmer must see what can be done to increase wheat and hay yields of his holding. Careful cultivation is the principal method of attaining this end. No hard and fast rule for the cultivation of the soil can be laid down on account of the various classes of land that are to be found, even on one farm. It is absolutely essential that every farmer should study and experiment in order to ascertain the best method of working the land on his holding. Generally speaking, ploughing should be commenced as soon as seeding operations have been completed, to allow ample time for rain to play its part in the settling down of the ploughed land. Two to three inches are deep enough for the land in this district to be ploughed. Do not plough the land while it is very wet, for it will be very hard and lumpy when worked back with the cultivator. If the land is turned whilst very wet instead of crumbling as it is turned, it will simply turn in blocks, leaving open spaces under the surface, allowing the escape of moisture, and making an imperfect seedbed.

The next implement to be used is a set of heavy harrows. These should be used before the hard crust has had time to form on the surface. If no weeds appear, and the surface is loose, the land should be left for a time, but if weeds show up, the cultivator should be set to work at once. If weeds are small, use a springtime cultivator, working at right angles to the ploughing, provided the paddocks are suitable; this tends to keep the surface from becoming irregular, as happens with constant one-way working.

The benefits to be obtained by using the springtime implement are:—1. Improvement of the seedbed; the fine loose soil shakes to the bottom, while the coarse and more lumpy soil works to the top, thus enabling one to break it down with the harrows when rain falls. 2. Lightness of draught; 10 horses are able to work a 35-tine cultivator quite comfortably. 3. One man with 10 horses can do a great deal of work with the springtime. The land being left ridgy behind this implement, it has a tendency to prevent drift. If the land is free from weeds and no heavy rain falls, the land can be left until autumn. If, however, rain falls during harvest, every opportunity should be seized of working the land. Summer weeds are bound to come, and the quickness of growth will cause no end of trouble. If weeds are strong and thick, use a bridle cultivator with 6in. shares or a disc cultivator.

Should rain fall at the beginning or up to the middle of April, it will give ample time to allow germination of weeds, and the land can be worked over before seeding. Land at seeding time should be cultivated as shallow as possible, in order not to injure the seedbed, and yet deep enough to destroy young weeds. Wheat should be drilled to a depth of 1in. to 1½in. and harrowed with a light set of harrows about three days

behind the drill. For this district, the month of May is the best seeding season, and will give best results if sown in June. Later on, the ground is too cold, the seed takes longer to germinate, and the plant is weak when cold wet weather sets in. The earlier sown crops, however, will have firmly established themselves, and will be prepared to fight against hardship. Let us all try and improve our system of cultivation. Each year do a little experimental work of this class. Read and study all papers on this subject, then we will be able to realise what there is yet to learn on this most important question.

"The paper contributed by Mr. Chynoweth is one of the best on the general principles of soil cultivation that I have heard at an Agricultural Bureau Conference." In these terms Mr. W. J. Spafford (Deputy Director of Agriculture) congratulated Mr. Chynoweth on the paper that he had presented to the Conference. Only on one point did he disagree with the writer; that was to his references to the value of the springtime cultivator for soil working. It was nothing but a glorified harrow. To successfully grow wheat, the farmer should maintain a level seedbed underlying the loose surface soil, and there was no springtime that could do that. Referring to summer fallowing, Mr. Spafford said it was worth while where land is very weedy and on those farms where livestock were not kept in any great numbers. In the reverse case, where large numbers of livestock were carried on farms in South Australia, the value of the feed grown on the land would more than compensate for any increase in crop that might be obtained as a result of summer fallowing.

THE BEST TYPE OF HORSE SUITABLE FOR GENERAL FARM WORK.

[THOS. BODDA, Boor's Plains.]

There is, in my opinion, only one horse suitable for general farm work, and that is the Clydesdale. Uniformity of type has long been a marked characteristic of the Clydesdale, and there is no breed of heavy horse so famous for its quality, cleanness of joints, hardness of bone, cleanness and correct setting of hock, and length and slope of pastern, whilst, as for action, the Clydesdale is unrivalled. Main points required when purchasing or breeding this type of horse:—

The height should range from 16½ hands to over 17 hands, and when fully matured, should be evenly balanced. Viewed from the side, the body should show plenty of depth and from the front or rear should appear broad and thick. The depth of body, through the chest, and the length of the leg, should be much the same, which proportions would give an animal a "low set" appearance, bringing his weight comparatively close to the ground, thereby enabling him to use it to the best advantage.

The head should be in proportion to the body: neither unduly large nor too small, with little superfluous flesh. The face may be straight or slightly Roman nosed, the contour of the former being the most pleasing. There should be plenty of width between the eyes, and the forehead should be slightly arched, tapering away from above the eyes to the poll. The ears should be pointed, of medium size and thin of texture, having a covering of fine hair.

The neck should be of moderate length, muscular yet not too thick, arched and well laid into the shoulders. A good head, neck, and shoulders denote character, giving the animal a good outlook.

The shoulders should slope at a good angle. A straight-shouldered horse, when used in heavy work, has an inclination to foot trouble. They should be fairly wide, well muscled, and the top should be carried close to and tapered into the back. The arm of the Clydesdale should be comparatively short, wide, and muscular. It should form a strong support to the shoulder, extending well back and close into the body at its rear part. This places the leg sufficiently under the body to give the desirable position and action. The knee, viewed from the front, should be broad and flat, tapering to the cannon, and, viewed from the side, should show a straight direction and not back.

The cannon should be long, wide, flat, lean, and shaped like the back of a razor. *The tendons* should show prominently. The long hair or "feather" should spring from the back of the tendon, and not from around the sides of the cannon. It should be soft

to the touch and straight. *The fetlock* should be wide viewed from the side, and narrow viewed from the front, fine and well directed. *The pastern* should be fairly long and sloping, to relieve concussion, in the course of action. A horse with a short, upright pastern has a more stilted gait and a greater tendency, when in action, to bring the toe to the ground before the heel, and when worked on hard roads, the legs tend to swell. Foot diseases are more common in horses having upright pasterns than on those of greater slope. A good, sound, healthy foot is essential, and in this respect the Clydesdale holds pride of place amongst draught breeds. A good hoof head, with wide open heels, and strong quarters, is essential, otherwise a horse has a tendency to develop unsoundness.

The chest should be deep, wide, low, and of large girth, indicating strong constitution, with ample space for the vital organs. The back should be short, broad, and strongly supported, and slightly inclined upwards toward the rump. *The loin* should be short, wide, and strongly muscled. This portion of the back should be as wide as possible, and the ribs long and deep, well sprung, and close together.

The hindquarters are the great source of driving power. The hips should be wide (but in harmony with general body proportions), and well muscled. *The rump* must be long, as seen from the side, wide as viewed from behind, and with attractive yet sloping arch from hips to the setting of the tail. It is important that the tail be attached high. *The thigh* should be short, but heavily muscled. *The hock* is one of the most important points in the body, as it is in this joint that the strain on the muscles, during action, is concentrated. The hock, therefore, should be broad viewed from the side, and narrow viewed from the front, its point being prominent, and the joint as a whole well supported by a wide cannon below. The hocks should be turned in slightly, and be fairly close to each other. The hind cannons, like the front ones, should be broad and thin, and they should be perpendicular or but slightly sloping forward. When they are too far forward they bring about a condition known as "sickle-hocked." The hind fetlocks, as in the case of the front ones, should be wide, whilst the pasterns are less oblique than those of the forelegs. The hind feet are somewhat smaller than the front ones, not so round, but with good hoof heads, and wide open heels. The hind legs, like the front ones, should be properly set into the body, not on the outside of the quarters, but well under, so that the muscles on the quarters project wider than the muscles on the thighs; the latter should be fairly close together, not straight down, but incline to the rear of the animal, and the toes of the hind feet should incline slightly outward. There should be a good length from the point of the hock to the ground.

The action of the Clydesdale should be even; that is, his fore and hind action should be in unison. He should plant his hind feet forward as deliberately as his fore ones, which should be evenly carried forward. In trotting, the horse should bend the legs at the knees and hocks, and, from a hind view, the inside of the hoofs (or shoes) should be seen at every step.

It is unreasonable to expect that farmers can purchase all their requirements of this type of horse. The best way is for them to secure one or two good mares, and breed only from high class sires. If unable to purchase the mares, farmers should select the best they have and mate with high class sires. In this way they will soon have a better type, and one which will be faster, and therefore do more work than those we find on the average farm at present.

MILK FEVER.

[L. H. MOAR, Paskeville.]

Milk fever is a common and, until fairly recently a frequently fatal disease affecting cows in all large dairying districts of this and other countries. As it usually attacks the best milking members of the herd, and at a time when the milk flow is heaviest, the malady is one which has caused very severe losses to our dairying industry. It is, therefore, of the greatest economic importance that every dairyman should acquaint himself

with the simple and easy method of treating the complaint successfully by means of filtered air injected into the udder. This form of treatment is comparatively new, and it is so very simple and successful that every dairyman should obtain a suitable apparatus (one containing a minimum of rubber) and know how to use it; in case of emergency an ordinary bicycle pump and nipple from tube (well sterilised) will answer the purpose admirably. With this, however, the air is not filtered, and there is a danger of injecting germs as well. The operation does not require the services of a veterinary surgeon, but the advice of a professional man may be of great value, in the case of complications.

The common name of this malady, "Milk Fever," is erroneous and misleading. In reality, fever is usually absent; instead, there is generally a reduction in temperature. There are a number of names for the complaint, *i.e.*, calving fever, parturition fever, etc.

Milk fever is a disease of well nourished, heavy, milking cows; it usually occurs during the third to fifth calf, and may be easily recognised by the suddenness of the attack, the complete paralysis of the animal, and the loss of sensation, which follows closely the act of calving or parturition, and death usually follows in 12 to 24 hours if not treated quickly. One attack usually predisposes the animal to a recurrence of the disease. The complaint may occur at any period of the year, but is most common in the spring. Other animals seldom have the complaint.

There are few diseases among animals regarding the exact cause of which more widely different theories have been advanced than that of milk fever. The causes may be divided into two kinds: predisposing and direct. Experience shows one of the most prominent predisposing causes to be the great activity of the milk secreting organ—the udder. This organ is most active after the fourth, fifth, and sixth calves, and this is the time of life when the vast majority of cases occur.

The disease is almost unknown in heifers with the first calf, and decreases steadily in frequency after the most active milking period, namely, the sixth calf, has passed. It is rarely, if ever, met with in pure beef breeds, such as Shorthorn, Angus, and

Bone Manure

Hereford, while it is very common in the heavy milking strains, as the Holstein, Jersey, and Guernsey. There are many theories regarding the direct cause, such as the absorption of toxins from the uterus, which causes paralysis, but nothing definite has been ascertained.

DIAGNOSIS.

This disease in its typical and most common form is comparatively easy to diagnose and easily recognised. It usually comes on about two days after calving, and seldom occurs after the second week. It has been known to occur a few days before calving.

At the onset of the attack there is usually excitement; the cow is restless, treads with hind feet, switches the tail, stares about, or walks uneasily and unsteadily and shows colicky symptoms. This is followed in a few hours by the coming paralysis indicated by a staggering gait, especially in the hind legs, and by weakening of the knees and fetlocks of the front legs; the animal becomes quieter, and staggers more, and becomes weaker; it ceases to worry about its calf, and finally goes down, and is unable to rise. The cow lies perfectly still with eyes partially closed, and the sense of feeling vanishes. Flies can swarm on the eyes and anywhere on the body and are unnoticed. While down, the patient assumes a characteristic position, which is of great assistance in diagnosis. The head is turned around to the side—usually the left—and rests on the chest, causing a peculiar arching of the neck. If the head is drawn straight, it immediately drops back again when released. The body usually rests lightly on one side, with the hind legs extended forward and outward, and the fore legs doubled up in their usual position. There is paralysis of the muscles of the throat, so that swallowing is impossible, and if drenching is attempted there is great danger of fluids going into the lungs and setting up pneumonia. In fatal cases the animal may remain perfectly still and die in a comatose condition from complete paralysis of the nervous system, but more frequently there is some agitation and excitement prior to death with tossing of the head. Death, like recovery, usually sets in from the eighteenth to the seventy-second hour after the onset of the complaint.

TREATMENT.

Anderson and Schmidt were the discoverers of the simple treatment, and they found the usual period of recovery to be about six hours, and very few cases required a second injection, and only an isolated case a third. Previous to the air injection, the hands of the operator and the udder of the cow should be thoroughly cleansed. The latter must be kept from coming in contact with the ground. The tube should be boiled for some time before it is placed in the teat. When fully prepared for the operation, carefully insert the tube into the teat, and pump air into it, while gentle massaging will assist the air to enter right into the full depth of the udder. The quarter should be well distended and care taken to prevent the air from escaping by tying a piece of broad tape around the teat. The other quarters of the udder should be treated in a similar manner.

In case the air is absorbed, and no improvement is noted within about five hours, the treatment should be repeated. The cow is usually able to get up on her feet within an hour (sometimes a quarter will suffice), and soon after the tapes should be removed, as the tips of the teats are then able to retain the air. The animal should not be milked for about 24 hours. The calf should not be allowed to suck. While this method is an easy one for the dairyman to adopt, he cannot expect to have the same results as a veterinary surgeon. In many cases it will be found that the injection of air into the udder will be sufficient to combat the disease without other treatment, but it is always advisable to study the symptoms of each individual case and administer medicine accordingly.

As a preventive, it has been found that by allowing a small quantity of milk to remain in the udder after each milking for about a week after calving, that the number of cases of fever has greatly diminished.

PROFITABLE FARMING ON A SMALL HOLDING.

[B. P. DUTSCHKE, Kilkerran.]

Farming is a business, and the successful farmer (on a small or large holding) must first of all be a business man. He follows his vocation primarily for the profit he can make out of it, and therefore he, like other business men, should aim to get the greatest possible returns for labor and money involved. It is not enough to simply grow crops; they must be produced to yield a profit on the money invested. To succeed in this respect, the farmer must be thoroughly acquainted with every detail of his occupation and endeavor to prevent needless waste, but at the same time he must remember that it is a good business principle to spend a pound whenever he can see that it will come back to him with interest.

Agriculture is Australia's primary industry; therefore the welfare of our country is largely dependent on the man on the land, and if he fails in his work, the result would be disastrous. It should, therefore, be the objective of every farmer to utilise his land to the fullest extent. This can be done by working the land judiciously and by following a proper system of rotation cropping. The intelligent and deep-thinking farmer will always try to devise ways and means by which to work his farm more economically, efficiently, and profitably.

A farm containing 500-600 acres could be called a small holding, and would be large enough for one man to make a good profitable living and bring up a family, provided the land was of good quality and in a district which had a good rainfall. Of course, 500 or 600 acres might hardly be sufficient for one man to carry on profitably in a district consisting of light soil and also with a light rainfall. However, the farmer who has a small farm in a poor district may still be able to carry on profitably, but it is evident that a farm in a district which contains first-class soil and a good rainfall would return greater profits, provided it was properly managed. Low yields are not always due to poor soil and lack of rain, but very often to bad management and lack of agricultural knowledge.

The holdings should vary according to the class of soil and rainfall in the different districts. In a locality containing fertile soil 500 or 600 acres may be considered a small holding, whereas in another part where the land is less fertile 700 or 800 acres would be called a small farm. However, whatever the acreage may be which constitutes a small holding, to farm profitably on such a holding, the farmer must take a keen interest in agriculture and not go about his work in a haphazard manner and trust to luck, but put his whole energy into the business. A 500 or 600 acre farm could be worked by one man, and if the work is done properly, it should be sufficient to keep him out of mischief. Consequently, the man on a small holding is not forced to employ labor, which, except at harvest or seeding time, is nowadays a big and very often an annoying item.

It is of vital importance that the plant should be in comparison with the place. The purchasing of large and expensive implements for the sake of finishing a few days sooner would hardly be a payable proposition, but nevertheless, the plant should be kept up to date. All machinery, farm buildings, fences, &c., should be kept in good order; this also tends to profitable farming.

There are two methods of farming well known to us, namely, horse and mechanical power. Tractors are to be found on most farms, although there is a general tendency for farmers at present to return to horses. The farmer dependent on horse power should not keep more horses than are required to work a small farm; unnecessary horses require feed and attention even whilst idle. A team of 10 to 12 good horses would be sufficient to do the work on a 500 or 600 acre farm. Likewise, the man who is solely dependent on mechanical power to work his farm should buy that type of tractor which is best suited for the class of soil in his district, and has some of the main features which a tractor should have, such as durability, accessibility, power, and so forth. Of course, care should be taken not to purchase a bigger tractor than is required to do the work on the small holding. At the present time, tractors have displaced horses on many farms, but owing to the present high price of fuel, tractors are costly to run and

depreciation is heavy, and it is problematical as to whether the work on the majority of farms, particularly the smaller ones, could not be more profitably carried out with the use of horses.

THE VALUE AND IMPORTANCE OF SIDE LINES.

A small but good flock of sheep would also add to the profits of a small farm. Every farm, whether large or small, should have its flock of sheep. They are not only valuable as far as domestic purposes are concerned, but they are also of great value in keeping the land clean. Sheep are very little trouble, and if properly fed will return a handsome profit from the selling of lambs and wool. The most popular system of agriculture is mixed farming, and this can also be adopted with success on a small holding.

On account of the exceptionally low prices ruling for our main products, wheat and wool, the farmer will be compelled to pay more attention to side lines. With the modern machinery and scientific methods we now have at our disposal, farming on a small holding is quite profitable. Science has done much to explain how the fertility of the soil can be conserved, and with the application of scientific methods to the farming of the future, still greater and better results may be achieved. One of the most common faults among farmers is the accumulation of more land than they can properly cultivate. Many thousands of Australian farmers are struggling to-day under a heavy load, mainly interest on mortgages granted in payment for land purchased in addition to the original farm. Had the farmer been content with a small acreage, the position would not be so acute. It would certainly be a benefit to Australia if the farms were smaller, thus peopling the country and creating a greater market for home consumption. It would improve the social life in the various communities and make country life more interesting. Any step taken towards populating the country and increasing production is a step towards strengthening and consolidating Australia and the British Empire, and it is the only way that a hold can be kept on this country.

If Australia wants to keep her place in the world's markets, producers will have to cut their costs of production, and at the same time increase production by using scientific methods. A sure way to reduce costs of production is to increase the yield per acre. As with the factory, so with the farm, i.e., the greater the volume of production the less the cost per unit or bushel. Mr. Scullin urged the farmers to grow more wheat, to which they readily responded; but the trouble is that farmers usually use more, and not less, acres on which to do it, and instead of decreasing they increase the bushel production cost. It is a known fact that small acreages, more intensive cultivation and fertilization, bring about bigger yields and larger profits, for it is intensive and not extensive cultivation that pays best. A farm capable of producing 50bush. per acre which only grows 20bush. is an unsound economic unit. We must fertilise sufficiently, otherwise we do not farm as well as we can. It has been said that good land is like a good bank account—the more you deposit in it the more you can draw out. Yet some farmers do not realise this and follow mining methods rather than farming methods, and soon deplete the soil. It is undoubtedly a most short-sighted policy and should not be practised.

One of two things must happen if production is to continue in this country in the future: either prices received by the farmer must be higher or the cost of production lower. Unfortunately, many farmers will be unable to put in a crop this year unless they receive monetary assistance. Seasons come and go, and the land has to be cultivated and drilled. All who possibly can should put in a crop, and it seems the only way in which we can meet the situation is to endeavor to produce our crop as cheaply as possible. But some one may say, "What is the use of producing more of a crop that is unsaleable at anything like a remunerative price?" The answer, of course, is the higher the yield of any particular crop the less cost to the farmer, and consequently the less the loss on that particular land. The present state of affairs is an incentive for the farmer to make certain he obtains the highest possible returns from the land he has under cultivation.

Do not despise the small fields and crave something bigger, not realising that you have as much as you can properly care for. Save the fertility, renew it, treasure it. It is the source and support of our agricultural wealth and our national greatness.

ECONOMY ON THE FARM.

[R. H. BURNS, Arthurton.]

The subject under discussion is one which calls for very serious consideration in view of the serious depression which is by no means a local trouble only, but has become almost world wide. Opinions differ as to how long we may have to wait before things will adjust themselves, but it is generally recognised by prominent business men that it will take five years to establish business on a sound footing again. We surely are justified in expressing the hope that the unsatisfactory financial position is now at its worst, and that the period of reconstruction will commence forthwith. The better times to which we are looking forward can be either hastened or delayed by the method adopted by those to whom our destiny is largely entrusted. While Governments and the powers that be must of necessity play a big part in this scheme of reconstruction, it must not be overlooked that the country is almost entirely dependent on the efforts put forward by primary producers. Overstocking should be very carefully guarded against, and farmers should make sure that they have a plentiful supply of fodder; it is better to err on the side of understocking than run any risk of having stock above the number which one can keep properly fed. In these days of low prices it appears imperative that we undertake a system of mixed farming, making cereal growing, of course, the main object.

Economy consists in getting the best return per acre, and the highest price for the produce, not in getting the largest area under crop at the least outlay. Sidelines are of utmost importance, and these should be handled in a systematic way. Pigs that are well bred are well worth the extra cost, and the same applies to cows, sheep, and poultry, which if properly kept can be a source of income of no mean value, as can be proved if careful records are kept. It behoves all of us in our own interests and that of our country, of which we should be justly proud, to practice the utmost economy, and by diligence win our way back to prosperity.

DAIRY CATTLE IMPROVEMENT ACT, 1921.**SALE OF PUREBRED BULLS**

Dairymen are again reminded that on and after July 1st, 1931, no bull will be accepted for sale under the Government Subsidy Conditions unless its dam has qualified under the present butterfat standards. It is suggested, therefore, that persons who desire to sell, under subsidy, bulls which are eligible only under the old standards, should effect the sales at once.

DEPARTMENT OF AGRICULTURE.

MAY 1st, 1931.

People generally are beginning to realise how much the country depends on the products of the soil, and the farmer has seriously to be regarded as a national asset.

The prosperity of Australia undoubtedly depends largely on the size and value of her exports—wool, wheat, and fruit forming by far the greater part of Australia's export products.

As the farmer is obliged to sell his goods in the open markets, and thus has to compete with the many countries which can boast of big wheat-producing areas within easy distance of the great populations of the world, it can be readily seen that the farmer's only hope in an attempt to retrieve his position is to co-operate wherever possible in the handling of his goods, both as a buyer and seller, and do his utmost on the farm to economise and thus reduce the cost of production.

The salvation of the wheat industry can only be brought about by a fixed determination on the part of the farmer to stick to his guns—or his ploughs—and carry out a very careful system of economy.

It is imperative that we should avoid all waste during years of plenty and when money is plentiful. It seems to be one of the laws of human nature that we grow a little careless and actually waste at times what at some future date we wish we could have returned to us. Feed is wasted which could have been stored, and were this practised, if only in the matter of building a stack of straw each year in the flush periods, South Australia would never be faced with the atrocious losses which accompany the droughts which periodically leave such devastation in their trail.

The purchase of luxuries has been overdone in the past few years, whether they adorn the inside or the outside of the home, and it is necessary to guard against over-capitalising the farm, and where practicable to build up reserve funds for lean periods.

The successful farmer must at all times be prepared to have on hand efficient and up-to-date machinery. It is false economy—and this must be avoided—to refrain from this necessary outlay and continue with obsolete machinery which must in the end prove a fruitful source of waste, at least indirectly. It is not advisable to purchase surplus machinery, as this would mean so much money lying idle, and this represents quite a handsome sum in these days of high-priced implements.

Neglect is one of the chief causes of leakage in the costs of production. Valuable machinery is often purchased and is not provided with suitable protection immediately it has done the season's work. The purchase of paint and its application is an important item which farmers generally are apt to overlook. Repairs to machinery are so often of the makeshift variety, and temporary repairs are so often regarded, when once fixed as permanent, that the time comes all too soon when the farmer is faced with a big repair bill, because he did not immediately procure the correct replacement.

The systematic use of good oil for the different machines plays a very great part in economy, and when a man boasts of the small quantity of oil he uses in a season it will generally follow that he is faced with the expense of new machinery, while the careful man finds his machine good for many more seasons—the extra time and money spent on lubrication is well worth while.

The motor car and lorry play such a prominent part on the farm to-day, and their purchase and upkeep represent such a large sum of money, that the farmer is obliged to practice the strictest economy in regard to the operation of these units.

Most of us are guilty of using our cars more than we should in view of the times, but by paying careful attention to tyre inflation, oiling, and keeping repairs to a minimum, running costs can be considerably reduced. Fuel consumption is a most important item, and the careful adjustment of the carburettor, coupled with careful driving, can reduce considerably the cost of this particular means of transport. The tractor which on many farms to-day plays such a great part in production, needs the utmost care and attention in view of the heavy work expected of it. From experience I have learned that by a systematic overhaul twice a year, and the use of a good quality oil, changed at the correct periods, and loads kept within reasonable limits, a tractor will perform many years of useful service. Here again the careful adjustment of the carburettor can mean a considerable saving on a year's operations.

"LUCERNE-GROWING IN SOUTH AUSTRALIA."

[By W. J. SPAFFORD, Deputy Director of Agriculture.]

(Continued from page 953).

UTILISATION OF THE LUCERNE.

Not only does the Lucerne crop produce a very high tonnage of dry matter per acre, and much more total digestible nutrients than do most other forage crops, but the forage is so very rich in digestible protein that it is specially valuable for certain of the domesticated livestock, and if the most is to be made of this foodstuff it should be utilised in a proper manner. Although very heavy yields of forage are secured from the crop, the stems of the Lucerne plant are comparatively fine, and so it offers no physical difficulties to any class of farm livestock, all being able to eat it without discomfort, in any stage of its development. For the same reason, it can be easily made into hay, without the cured material being in any way objectionable. The crop can be manufactured into and stored as silage, but as it is so very rich in protein, and the losses of protein in ensilage-making are fairly high, it is on the whole much too valuable a crop to be stored in this way, unless it is the principal forage crop grown, and stored succulent fodder is needed on the farm. All farm livestock do well on Lucerne, either in the green state, as ensilage, or as hay, but because of its high protein content it is an exceptionally good forage for the production of milk and for young growing animals, and is more suitable for this purpose than for the fattening of livestock, although it does this readily in a warm climate, such as is ours.

That Lucerne is a high-class forage is easily seen, by an inspection of the following Table, where its composition and digestibility as green forage, ensilage, and hay are compared to other well-known foodstuffs.

MEGGITT'S LINSEED MEAL.

The seasonal reduction during certain months of the year in the output of milk, cream, butter, and cheese, can definitely be checked by the use of Meggitt's Linseed Meal.

Meggitt's is a highly concentrated food, rich in essential milk producing and body building protein, and conditioning linseed oil in the correct proportions.

Sold in any quantity, from one bag (100lbs.) upwards.

Obtainable from any Dairy Produce Factory, Grain or Chaff Merchant, or direct from—

ELDER, SMITH, & CO., LIMITED,

SELLING AGENTS IN SOUTH AUSTRALIA.

(a) European analyses and digestibility results.

(b) South Australian samples.

Even after the proportions of the various nutritive substances are known it is extremely difficult to make a proper comparison of foodstuffs if they are of different types or if they are to be used for different purposes. For instance, it is a fairly simple matter to compare foodstuffs if they are to be used for fattening purposes or for maintaining the condition of the animals using them, provided they do not belong to extreme types, like roots on the one hand and grains or oil cakes on the other, but if the feeds are to be used for the production of fat on some animals and the production of milk by others, the making of a comparison is by no means easy. In this connection it might be pointed out that the nitrogenous part of the foodstuffs—the *protein*—is of great value in aiding the formation and secretion of milk, but as a fattening substance is not so good as the starchy portions of the feed—the *carbohydrates*—and is a long way behind the *fats* of the feed for this purpose. Because of this, some feeds which are comparatively rich in *proteins*, such as the leguminous hays, are especially valuable in the production of milk, but when compared with other hays not so rich in nitrogen, from a fattening point of view, they are no more valuable, and in some cases are less so. In the above table the nutritive value of the various foodstuffs can be clearly seen, because the *Starch Equivalent*, as calculated according to Kellner's method, gives a correct comparison as to the feeding value of similar foodstuffs when used for fattening or maintenance purposes, and the proportion of *digestible protein* shows how valuable they are for the production of milk, &c. Lucerne is seen to be about as good as Oats and Red Clover for fattening purposes, whether used as green forage, ensilage, or hay, and better than either of them for animals in milk, and on the whole is one of the best of the cultivated green forages known in civilised countries.

LUCERNE AS GREEN FORAGE.

Lucerne is easily the best plant for the production of green forage we have yet seen for South Australian conditions, and is particularly valuable for cutting and carting to the animals being fed upon it. It is very eagerly eaten by cattle, sheep, horses, pigs, and all kinds of poultry, and without exception they all do well on it, whether used with the object of producing meat, milk, or eggs.

GRAZING THE LUCERNE CROP.

It is generally recognised that thick stands of Lucerne, making strong, luxuriant growth, either under irrigation or when on a close water-table, cannot be grazed with safety by cattle and sheep unless great care is taken with the animals. Ruminants are very liable to develop "bloat" when grazed on sappy Lucerne, particularly if it is covered with dew or rain, but the danger is considerably less on the lighter stands and weaker, drier growth commonly met with when Lucerne is grown on sandy soils, or on the ordinary wheat-growing lands of the country. It is usually found that cattle or sheep which have access to other kinds of pasture as well as Lucerne, or if they can always get at a supply of dry feed, do not suffer from "bloat" to any great extent. Whatever condition the Lucerne is in, when about to be grazed by cattle or sheep, the animals should be gradually accustomed to it by making sure that they are not hungry when they first go on it, and that they are only allowed to remain for a short while the first day, a little longer the second, and so on, taking about a

week before allowing them to remain the whole time. On no occasion during this process should they be allowed on the Lucerne while it is covered with dew or rain. Dairy cattle and mature sheep are very liable to "bloat," nevertheless they do remarkably well on the forage if carefully watched for this trouble, the cows remaining in full production without the need of other foodstuffs, and the sheep producing wonderful lambs and fattening very readily. Lambs are not at all liable to be affected by "bloat" even when grazed solely on Lucerne. For horses having a spell, or those doing light work only, Lucerne is almost an ideal grazing crop, but it tends to rather loosen and soften horses on heavy work. There are not many forage plants that can be economically grazed by pigs, but Lucerne is an exception to the rule, and when pigs are given a grain ration while grazing the Lucerne, the very best quality of pork is produced. It is almost an ideal foodstuff for brood sows, and if fed to sows with litters they rear their young well, and carry their condition right through. The stand of Lucerne is not injured by pigs unless too many are put on it at one time, or they are left on for too long a time. If no more than 20 pigs per acre are allowed, the Lucerne plants will not be damaged much provided that the pigs are receiving a liberal allowance of grain, but if more are to be used they should be shifted to other plots before they root up the plants.

Grazing the Lucerne tends to shorten the life of the stand, because it is thinned out much quicker than if stock are never let on it, and if great care is not shown this killing of the plants will be brought about very rapidly.

To get the best out of the crop without injuring it:—

- (1) The crop should be well established before stock of any kind are grazed on it.
- (2) The animals should be moved to another field, before they damage the stand.
- (3) After resting the field, the plants should be allowed to make growth about a foot high before stock are again put on it.
- (4) If possible, the crop should be fed down rapidly, and the stock moved on: this can only be done if the stand is divided into small fields.

CUTTING AND CARTING LUCERNE FORAGE.

Where maximum returns are to be got from the Lucerne crop grown for green forage, it should be cut and carted off the land, and livestock should never be grazed on it. This is not always the most economical way to manage the Lucerne crop, but when handled in this way much more forage is produced, the stand lasts a lot longer, and animals do not suffer in any way from feeding on the cut forage. Where dairying is being carried out, all luxuriant-growing Lucerne should be cut and fed to the cows in racks, when the animals will give full yields of milk, and the danger of loss of cows from "bloat" will be done away with. The Lucerne should be cut when the fresh shoots are starting from the crowns, and so long as the cutting is done in a regular rotation throughout the growing period of the crop, very little of the crop will get ahead of the mowers. Poultry can profitably utilise a relatively large amount of Lucerne, particularly for producing eggs, but before it is fed to them it should be chaffed so that there is no waste of such a valuable foodstuff.

LUCERNE AS HAY.

For animals producing milk there is no hay the equal of that made with Lucerne, for it is highly digestible, contains a large amount of protein, ash, and lime, and is so palatable that animals are encouraged to eat large quantities of it. The stems of the plants are relatively thin, and when made into hay they remain tough rather than brittle, and so their size and texture are ideally suited for hay, and are not, in any way, objectionable to farm livestock. The quantity of hay secured, its palatability and digestibility, are very largely dependent upon the time the crop is cut and the methods employed in curing it, and as it is necessary to take certain precautions if a high-class sample is to be manufactured, a knowledge of the requirements in this connection is essential.

WHEN TO CUT THE LUCERNE CROP FOR HAY.

The Lucerne plants must be cut when they reach a certain stage of development, because not only does this control the quantity and quality of the hay received from that cut, but it affects all future cuts, and eventually decides what shall be the life of the stand. Lucerne grows to a certain height, then begins to flower, and at the same time a fresh lot of shoots, which will eventually develop into the next crop, commences to grow from the crowns of the plants. At this time also, the lower leaves begin to fade and soon fall to the ground. Sometimes the plants reach the flowering stage without the flowers actually opening, and they remain with the buds showing for some time, but in the meantime the shoots from the crowns have started. Again, it occasionally happens in cool weather that the lower leaves fade and drop before flowering has started or the new shoots appeared. It is generally recognised now-a-days that the greatest quantity per season of the highest quality of hay is obtained if, before the mowers are put in the crop, the new shoots are allowed to grow just sufficiently high so that they will not be cut off by the mowers. This stage is usually reached when about one-tenth of the crop is in bloom, and so as a rule this indication can be taken, but it is much safer to carefully inspect the crowns of the plants and cut the crop when the new shoots have made some little growth. If the new shoots are cut when mowing, the next growth is usually considerably reduced in quantity and its maturity delayed. Once the leaves begin to fall the stems rapidly become fibrous and hard, so on those occasions when the leaves begin falling before flowers or new shoots appear, the crop should immediately be cut to enable good quality hay to be made and to encourage the next growth. The leaves are much richer in protein, higher in nutritive value generally, and lower in fibre than are the stems, so it is essential that they be saved if at all possible.

TABLE II.—*Analyses of Leaves and Stems of Lucerne.**

| | Leaves. | Stems. |
|-----------------------------|---------|--------|
| | %. | %. |
| Ash | 11.07 | 8.17 |
| Crude Protein | 25.45 | 12.42 |
| Crude Fat | 3.18 | 1.36 |
| Nitrogen-free Extract | 44.50 | 41.09 |
| Crude Fibre..... | 15.47 | 38.78 |

"Alfalfa Production in Kansas"—R. J. Throckmorton & S. S. Salmon.

When the crop is allowed to pass the ideal stage and reach full bloom before cutting, the hay made is usually fairly good, but the yield secured is generally less during the season, because the next crop does not start away so quickly as one cut earlier.

TABLE III.—*Yields of Lucerne Hay Cut at Different Stages.

| Time of Cutting. | ANNUAL YIELDS. | | | | | Mean Yields. |
|-------------------------------------|----------------|-------|-------|-------|-------|--------------|
| | 1922. | 1923. | 1924. | 1925. | 1926. | |
| | lbs. | lbs. | lbs. | lbs. | lbs. | lbs. |
| (b) Early or frequent cutting | 8,100 | 5,105 | 5,392 | 5,392 | 5,080 | 5,814 |
| (a) Normal cutting | 5,490 | 5,985 | 4,860 | 4,860 | 5,240 | 5,287 |
| (c) Delayed cutting | 4,750 | 4,855 | 4,380 | 4,380 | 4,580 | 4,589 |

The stage of development of the crop at the time of cutting has a positive effect upon the duration of the stand. Cutting in advanced stages maintained a better stand throughout.

TABLE IV.—*Condition of Lucerne Stands Cut at Different Stages.

| Time of Cutting. | CONDITION EXPRESSED IN PERCENTAGES. | | | | | |
|-------------------------------|-------------------------------------|-------|-------|-------|-------|-------|
| | 1921. | 1922. | 1923. | 1924. | 1925. | 1926. |
| (b) Early or frequent cutting | 100 | 100 | 94 | 84 | 80 | 58 |
| (a) Normal cutting | 100 | 100 | 95 | 85 | 75 | 65 |
| (c) Delayed cutting | 100 | 100 | 100 | 92 | 88 | 85 |

* "Experiments with Alfalfa"—Martin Nelson, University of Arkansas.

(a) Normal cutting was gauged by more or less arbitrary judgment, because the behavior of blooms is not the same for each crop.

(b) Two or three weeks before normal.

(c) Two weeks after normal.

The above tables show that, although more hay is secured by cutting the crop frequently and before it has reached the flowering stage, the life of the stand is considerably reduced. Local experience is the same as that quoted, for it is found that continuously cutting the crop in the bud stage thins it out rapidly. If cutting the crop when immature is only done occasionally the stand does not appear to suffer, but it must not be carried out too often.

TIME OF DAY TO CUT LUCERNE FOR HAY.

It is a matter of common experience with lucerne-growers who make hay that external moisture, such as dew or rain, is harmful if present on the Lucerne any time from the cutting of the crop to the stacking of the cured hay. Because of this the cutting of the crop is never commenced of a morning until after the dew has dried from the plants. Most experienced growers cut the crop in the morning, being careful only to mow an amount that can be cocked, or at least put in windrows on the same day. Where labor is scarce, some growers cut the crop in the late afternoon and rake and cock it the next day before again commencing cutting. As showery, or even cloudy weather, delays the curing of the hay, and often leads to the production of poor quality material, cutting is sometimes delayed until the weather brightens up.

SETTING THE MOWER TO CUT LUCERNE.

In most places it is usual to set the mower so that the crop is cut as close to the ground as possible so as to get the maximum amount of hay, to force the new growth from the crowns instead of encouraging side shoots from the butts of the old stems, and to keep down the wastage of material which follows the cutting off of the short stubs left last time when the mower was cutting too high. Where cold winters are experienced it is usual to raise the cutting-bar of the mowers for the last autumn cut, so that stems about 6 in. in length are left to protect the crowns during the winter, but this is not necessary anywhere in this State. In those places where the soils are fairly saline, or where the irrigation water being used is approaching the danger point as regards salinity, enough stem should always be left to keep the surface of the soil shaded and so reduce the possibility of an undue concentration of injurious salts at the surface.

CURING LUCERNE HAY.

It has already been shown in Table II. that the leaves are easily the most valuable part of the cured hay as far as nutriment goes, and according to J. T. Willard, in the portion of Kansas Agricultural Experiment Station Bulletin 155, "Alfalfa," written by him, good Lucerne hay is composed of 58.75 per cent. stalks, 38.43 per cent. leaves, and 2.82 per

LUCERNE HAY.---Showing the mower at work cutting the hay crop, and the small, easily-handled cocks thrown together immediately after cutting.

cent. flowers, and so everything possible must be done to retain in the hay all the leaves carried by the plants. The leaves dry very readily, become brittle, and easily break off the stems, and so it is not a simple matter to cure the hay with a low loss of leaves, but because of the importance of retaining this portion of the hay, all operations connected with hay-making hinge on this necessity.

The Lucerne is usually cut with a mower, and the cut material is allowed to lie in the swath just long enough to become wilted, or, at the longest, until the exposed leaves are almost dry; and it is then raked up into loose and rather open windrows. If left too long in the swath the leaves become

thoroughly dried while the stalks are still sappy with moisture. When the hay has toughened a bit in the windrow, it is forked into cocks small enough so that they can be handled by one good forkful when carting time comes, or when the cocks must be moved because of excessive rain. The art of making good Lucerne hay depends on exposing it to the sun as little as possible, and allowing the air to do practically all of the curing. In this way hay of good color, sweet aroma, and high palatability will be produced. If exposed too much to the sun it leads to the production of bleached hay from which many leaves have fallen because they were dry and brittle, lowered nutriment and palatability, and loss of weight. If the Lucerne is raked into windrows, before even the surface has dried, and is then forked into cocks whilst still containing a good deal of moisture, the leaves continue to draw the water from the stems, and the whole mass cures evenly. If very hot weather is experienced at hay-making time, the windrows are made soon after cutting, and almost immediately the material is put into cocks, but if good, fairly cool hay-making weather obtains, the Lucerne will be in the swath two or three hours and in the windrows for a full half day. If unfortunate enough to strike cloudy, dull, weather it may take a couple of days before the hay is dry enough to put into cocks, and in the meantime it may have been necessary to turn the windrows over at least on the first morning after having raked them together. Light crops of Lucerne can be raked as soon as cut without any wilting, and in hot weather the material will go straight into cocks. The hay should not be put into cocks when covered with dew or rain, as there is a good chance of it developing mould. On irrigated land, or after a rain, it is often wise to move the cocks a couple of hours before stacking, so as to expose the damp hay on the bottoms, and so dry that portion. The hay is ready for carting when still tough and slightly damp to the feel, but if a handful is tightly twisted no moisture should be exuded from the stems. When it is necessary to make the hay in the most economical method possible all of the curing is done in windrows, and the labor of making cocks is dispensed with, in this way much time is saved, because in good weather the hay will be ready for stacking in from one to two days, whereas if cured in cocks it would probably take twice as long. If much rain falls during the curing process it often pays to leave the cocks until the outside dries, then shift them to a new spot alongside; breaking up the cocks and exposing the inside of them will lead to better drying, but more surface is exposed and many leaves are lost. Hay exposed to much rain is greatly damaged by moulds and fermentations and by the dissolving of soluble substances, as is clearly shown by the following figures obtained at Colorado Experiment Station, after three rains, totalling 1.76in., had fallen during curing:—

TABLE V.—*Losses Caused by Rain Falling on Lucerne Hay.*

| Hays. | Weight of Hay. | Ash. | Protein. | Fat. | Nitrogen-free Extract. | Fibre. |

LOADING LUCERNE HAY.—A mechanical loader picking up the hay.

STACKING THE LUCERNE HAY.

Great care is necessary to see that Lucerne hay is stacked when in the right condition as regards moisture, because if too dry much of the most valuable part of the hay—the leaves—is lost, and if too moist there is the danger of the development of decomposition and moulds, and in extreme cases it may lead to spontaneous combustion. It is usual with the best hay-makers to stack the hay as soon as it is possible to do so, and a common test is to take a handful of the hay from the centre of a cock and twist it very tightly, and although it may feel moist to the hands, if no sap is squeezed from the stalks it is considered perfectly safe to stack.

STACKING LUCERNE HAY.—A high-lift mechanical stacker being used to stack lucerne hay.

Hay wet with dew or rain should never be stacked, because it is even more likely to heat than if damp through being insufficiently cured; in this connection it is sometimes said: "Lucerne hay is more likely to suffer damage from moisture *on* it, than from moisture *in* it." Whenever possible Lucerne hay should be stored in sheds in preference to being stacked in the open. This provision is warranted because it is such a valuable foodstuff, and one which does not shed water well, and if stacked in the open it is necessary to thatch the stacks in some way. Wherever stored it should not be placed directly on the ground, for if this is done there is some loss through drawing sufficient moisture from the soil to lead to decay, and so dunnage or a layer of straw should first be put down on which to build the stack. In stacking in the field, with such a material as Lucerne hay, which rather tends to keep loose and open, it is absolutely essential that the middle of the stack be kept about 3ft. higher than the edges, all the way up from the ground until the roof is being built. When this is done the material slopes towards the outsides when settling, and then even if rain does get into the stack it will be led to the outside.

Where large areas of lucerne are grown for hay, most of the hay-making and stacking can be done by machinery. The hay is picked up by a

mechanical loader direct into the waggon, and is put into the stacks by an elevator or high-lift stacker.

If hay is stacked with a little too much moisture in it a slight fermentation will take place and the material will be of a brownish color instead of a bright green. This brown hay is relished by livestock, and some dairymen claim that better results are secured from milking cows fed on it than if ordinary green hay is used.

For home use there is very little disadvantage in some brownish coloration developing in the stored hay, but if the hay is to be sold it is essential that it be of a normal green color.

Some hay-makers follow the practice of sprinkling coarse salt throughout the hay during the operation of stacking, and although this is advantageous where poor quality hays of various kinds are concerned, to improve their palatability, it is not necessary for well-cured Lucerne hay. On the other hand, if there is any danger of an excess of moisture leading to fermentation in the stack, the presence of the salt reduces the risk of damage from this source. It is usual to sprinkle the salt into the hay at the rate of from 14lbs. to 28lbs. per ton of hay.

BALING THE LUCERNE HAY.

Where Lucerne hay is grown for sale, or when it is desired to cart it long distances, it is often the most economical method of handling, to press it into bales in the field where grown. The baling press is taken to convenient spots in the field, and sweep-rakes bring the whole cocks of hay.

LUCERNE HAY.—A push-rake helps considerably in handling the cured hay, especially in bringing the cocks to the press, when baling the hay in the field.

or loads from the windrows, right to the press, and it is there and then made into bales. Before the hay can be baled it must be dry enough to stack, and no risk can be taken of excess of moisture being present, because partially cured hay is always spoilt in the bale.

YIELDS OF LUCERNE HAY.

In the good lucerne-growing parts of the State, where the crop is grown specially for hay, the average yield should be about 5 tons per acre, being something over 6 tons per acre from the better fields in the irrigated districts, and around 4 tons per acre where it is grown on a close water-table. In these places the variation in yield from year to year is not very great, but where the crop is dependent upon the rainfall, or the water-table is a long way from the surface, or the underground water is very saline, the yield varies a lot according to the season. In districts where the average

LUCERNE HAY.—Pressing well-cured lucerne hay into bales at Wood's Point, South Australia.

annual rainfall exceeds 16in., and good cultivation and liberal manuring are practised, at least 1 ton of hay per acre per year should be expected, and some months of grazing as well. In sandy soils on a water-table not too far down, besides a ton of hay per acre, this grazing should be really good in most years, and should last for about five months.

FEEDING THE LUCERNE HAY TO LIVESTOCK.

For dairy cows and all other farm livestock producing milk, there is no hay made in a hot climate that can be compared to Lucerne. It contains sufficient digestible protein and lime to fulfil the requirements of milk production, is liked by the animals, and can be fed by itself without the stock becoming tired of it, and without them suffering in health or vigor. It should be fed to cows and sheep as long hay in racks, there being no need to chaff or otherwise treat it in any way, as is necessary with most other hays. For pigs and horses it is unnecessarily rich in protein, so should always be fed in conjunction with foodstuffs containing more carbohydrates. Pigs do much better if fed on Lucerne hay and barley or wheat than if the grain alone is fed to them. The most economical way to feed the Lucerne hay to pigs is to supply it to them in strongly constructed racks and allow them to take all they desire. If at the same time the pigs get their grain from a self-feeder, they will develop very rapidly, and produce pork with the correct proportion of lean to fat. Horses

waste much of the valuable protein in digestion, if fed on Lucerne hay alone, so it should never form more than part of their ration. From 10lbs. to 15lbs. of Lucerne hay is sufficient for any horse, if he is also receiving other foodstuffs. For working horses most feeds of Lucerne hay can with advantage be given as chaff. Lucerne-hay is a good foodstuff for poultry, and in most cases will cheapen the cost of the eggs produced.

Lucerne meal should always be bought on a guaranteed analysis, to ensure that it was not leafless hay that was ground up, and in any case it is doubtful if it has any advantage over Lucerne-hay chaff at an equal price, unless it be for young chickens.

LUCERNE AS ENSILAGE.

Lucerne is usually looked upon as being too good a foodstuff to be converted into ensilage, and in a general way it is contended that poorer fodders are good enough to supply the principal advantage of ensilage, *i.e.*, succulence, whilst those rich in protein should be stored so that this valuable constituent is not wasted. On the other hand, if Lucerne is the only green forage grown, it is usually of advantage to store some of it as ensilage, to supply succulent feed in the heart of winter and other times

STORAGE OF LUCERNE.—Making lucerne ensilage at Wood's Point, South Australia.

of shortage. Although there is some wastage of valuable material, Lucerne makes a first-class ensilage, much relished by livestock, and still rich in protein.

When making ensilage, the forage must be picked up as soon as cut and should not be allowed to lie on the ground for even a short while, and certainly not overnight. As a little extra water does not injure the ensilage, and, as a matter of fact, keeps the cut plants fresh for a longer time, it often pays to cut the crop when wet with dew or rain. It must be carted straight to the silo or stack, and be put into the receptacle or heap without delay. If to be put in a constructed silo the forage should be chaffed, but if to be stored in a rough hole in the ground, or in a stack, the forage as cut with the mower will not be further treated. When the silo is full it should immediately be weighted down with fencing posts,

stones, &c., and about 400lbs. to the square foot of roof surface should be applied. If manufacturing the ensilage in a stack the outside ring should be kept much higher than the middle, whilst building, which prevents the excessive bulging of the sides when the usual extensive settlement takes place. It is absolutely essential with stack ensilage that as soon as the stack is completed the weight should be applied, and for this form a weight of about 500lbs. to 600lbs. per square foot is required. A most suitable article to use to weight down ensilage, and one often obtainable on farms, consists of ordinary rough stones of a size readily handled and thrown by a man. With such material the weighting down can be done quickly and easily, and the weights can be thrown off again without trouble.

Success in ensilage making, particularly if made in a stack, is wrapped up with:—

- (1) Putting the cut fodder into the silo or stack whilst quite fresh;
- (2) filling the receptacle or completing the stack rapidly; and
- (3) weighting it down immediately the last load is put in position.

Lucerne ensilage can be fed to all farm livestock, in the same manner and in about the same quantities as is the green forage, with the exception that great care must be shown to see that no mouldy material is given to horses.

PRODUCTION OF LUCERNE SEED.

The production of good quality Lucerne seed in payable quantities is wholly dependent upon the weather conditions prevailing during the period from the pollination of the first flowers, until the last blooms have dropped. The seed crop might be spoiled by a rain falling when the plants are in bloom and before the flowers are fertilised. The same thing might apply through the intervention of cool weather at this time, by hindering the "tripping" of the flowers, and so reducing the number of flowers that are fertilised, and the occurrence of a frost about flowering time prevents the setting of seed. If very hot, dry weather is experienced during flowering time, in years when the soil is rather lacking in moisture, it leads to a light crop of seed containing many small, ill-developed seeds. So uncertain is the seed crop that growers are never sure that they are to obtain profitable returns until the plants are actually covered with pods carrying seeds. Because of this dependence upon the weather at flowering time, only those localities where these impediments to the setting of seed are comparatively rare happenings, can hope to economically produce good quality seed, and any lucerne-growing district so favored has a great advantage over others for this purpose. The favorable natural conditions obtaining in portions of South Australia have enabled this State to come to the fore in recent years as a producer of first-quality seed, and on the present showing it appears that great progress will be made along these lines in the future. The ideal conditions for the production of high-class seed are to be found where the Lucerne plants make fairly vigorous growth without artificial watering, and where plenty of sunshine and hot, dry weather are experienced in the summer. Where these climatic conditions exist and the water-table is far enough down, good seed can be secured from irrigated Lucerne, when the application of the water is strictly controlled.

Lucerne plants with plenty of room, so that all parts of the plants are exposed to the light and air, are the heaviest seed producers, and so thin stands of fairly vigorous plants give the best results. With thick stands the seed-pods are limited to the tops of the plants, because neither blooming

nor pollination are good on the shaded parts of the plants. Lucerne grown in spaced rows usually gives better crops of seed than when broadcasted in the ordinary manner or grown in rows close together.

As with most other leguminous plants, the flowers of Lucerne are fertilised by the blossoms being "tripped." This "tripping" usually consists in the pollen-carrying parts of the flower (stamens) being moved from their enclosed position alongside of the immature pod and being forced outside of the petals, at the same time releasing a shower of pollen. It is the "tripping" of the flowers that leads to their fertilisation, and so the setting of the seed. This is often brought about by insects alighting upon the flowers, but, fortunately, Lucerne is not wholly dependent upon insects to "trip" the flowers, for in some circumstances sunshine also leads to this

LUCERNE SEED.—Illustration showing a reaper-thresher harvesting and cleaning lucerne seed on the first occasion that this job was carried out in one operation in South Australia. The crop, which returned the very high yield of 420lbs of seed per acre, was grown by Mr. S. E. Mudge, of "Attunga," Hallett, South Australia, and was harvested in March, 1928. The machine used is a reaper-thresher fitted with a modification of the pea-harvesting front-piece.

liberation of pollen, but fertilisation by insects gives better results than self-fertilisation. To ensure the presence of plenty of insects, some seed-growers insist that bees should be kept near Lucerne fields from which seed is to be harvested, although in all probability bees do not play as important a part in this direction as do other types of insects.

Various methods of harvesting the seed are practised, but in a general way they consist either of cutting all the crop and then threshing the seed, or the pods only are collected. If the former method is followed the cutting of the crop is commenced when about two-thirds of the pods have turned a dark brownish-black color, but if only the pods are to be harvested, the seed crop must be more matured. In the seed-producing districts of this State where irrigation is not practised, it is usual to harvest the seed direct, either by doing the whole operation at once with a Reaper-thresher fitted with lucerne harvesting front-piece and special sieves, or by collecting the crop of seed with a stripper, removing and cleaning the seed with a winnower, and repeatedly passing the unthreshed pods through the threshing drum of the stripper, while it is being drawn behind a travelling conveyance which carries the pods to be threshed. If the whole crop is to be cut, small, loose sheaves are made when a binder is used, and they are

stooked until properly dry before any attempt is made to thresh the seed. If cut with a mower, the crop should be handled very carefully with forks and put into rows, and finally into cocks so small that each one can be easily picked up as a single forkful when carting to the thresher. Small areas are cut with a scythe and dried with as little handling as possible. The best time to cut the seed crop is in the morning when the plants have dew upon them, because the pods are then tough and there is less danger of the shattering of the seed. The crop from small areas is often threshed by flail and cleaned by the wind and hand sieved, but larger lots are threshed and cleaned in ordinary power threshers adjusted with special sieves, or in clover-hullers made specially for the threshing, cleaning, and dressing of small seeds.

Success with the seed crop on irrigated areas is wholly dependent on having full control of the water supply, and in using the minimum amount that will keep the plants making slow, healthy growth. Rapid, luxuriant growth is required for hay crops, but such plants set little seed. If the previous cut of forage had been heavily watered there is often no need to irrigate the seed crop at all, but if a watering is necessary, the best time to apply it is after the seed has set, and the flowers have fallen.

Very rarely is the first crop of Lucerne ever left as a seed crop, because it is usually too rank, and the season of the year is too cool and damp to expect a good crop. Sometimes the second crop is allowed to mature seed, but more often best returns as to quantity and quality are secured from the third crop, which ripens its seed in this country, when the weather is usually dry and hot at about the end of February or in early March. When growers intend to leave the second crop for seed they usually carefully examine the plants immediately after flowering is completed, and if there is not a plentiful setting of seed, the crop is cut for hay, and the next growth is then left as a seed crop.

The amount of seed harvested varies a good deal according to the season, but at least 150lbs. per acre should be secured, and it may occasionally be increased above this quantity to as high as 500lbs. per acre.

The production of a full seed crop often shortens the life of some otherwise long-lived plants, but this does not appear to be so with Lucerne, and the stands last just as long whether all the growth is made into forage or a seed crop be taken every year.

DISEASES AND PESTS OF LUCERNE CROPS.

Fortunately, there are no diseases which do noticeable damage to Lucerne crops in South Australia, but there are a few pests which sometimes make their presence felt. Of these, the only ones of economic importance are Lucerne Flea, Boll Worm, and Dodder.

THE LUCERNE FLEA OR CLOVER SPRINGTAIL

(*Smynturus viridis*).

The Lucerne Flea lives and reproduces itself during the cooler and moister parts of the year, and in this State is active from the first winter rains in April or early May until the warm weather arrives in October. The insects are very active during that period and feed on a big assortment of garden and field plants, and are particularly fond of Clovers and Medics. They play havoc with the leaves of Lucerne crops left for winter feed, and with the first growth made in the spring, but no damage whatever to

the principal growths during the summer, and there is no evidence to show that the annual attack shortens the life of the stands.

The insects are small, soft, and wingless, being of a dumpy shape about one-twelfth of an inch long and almost as thick, and are of a greenish-yellow color, but vary a good deal in this regard between green, yellow, and even orange. They are able to jump a few inches by means of a forked, spring-like apparatus on the abdomen. In favorable seasons they become so plentiful that they arise before a person walking through affected crops, like a thin cloud of ashes. Their presence is noticed by the fact that the plants lose their general green color and take on an ashy-grey appearance due to the fact that the "green" of the leaflets is eaten right out. They eat the lower surface of the leaves, usually taking most of the green matter without

Photo by Dr. J. Davidson.

LUCERNE FLEA.—Showing upper-side and side view of *Smynturus viridis* greatly enlarged.

going right through the leaf, leaving them like skeletons, and of a greyish color. The females lay on the surface of the ground two or more batches of eggs in a season, of about 50 to 60 eggs to a batch, which in regular, cool, damp weather may hatch out in 10 to 12 days, but when the hot weather arrives the eggs remain dormant throughout the Summer, and hatch out when the autumn rains arrive.

When they are noticed in a Lucerne crop it should immediately be cut, or fed down rapidly, and if it is desired to keep the next growth free from the insects, the land should be sprayed with about 80galls. per acre of a mixture of 10lbs. arsenate of lead, 2 quarts of nicotine sulphate, and 500galls. of water. The Lucerne should not have stock put on it for at least three weeks after spraying, otherwise severe scouring of the animals might result.

THE BOLL WORM (*Heliothis obsoleta*).

Caterpillars of the Boll Worm are to be found every year in Lucerne, but they only occasionally do much damage. Sometimes they are in sufficient numbers to reduce the yield of forage, and they also lower the value of what is left, because they feed on the young succulent growth in

preference to the older leaves. The flowers of seed crops or even the seed-pods are attacked at times by these caterpillars, with rather disastrous results, because they leave very little seed when present in large numbers, and the crop by that time has passed the stage when good hay could have been made of it.

LUCERNE FLEA.—Spraying an affected crop after being grazed down by livestock.

These caterpillars attack practically all of the well-known cultivated crops. They are very widespread, and most countries or districts have local names for the pest. When full-grown they are about $1\frac{1}{4}$ ins. in length, and of a color varying between pale, yellowish-green to dark green, but are always striped along sides and back, the stripes varying from yellow, to green, to black in color. The larvae usually feed from three to five weeks, after which they enter the soil to a depth of about 4 ins. to pupate. In the summer the pupae stay below-ground from two to four weeks, but those of the last brood may remain in the soil for six months.

When forage crops of Lucerne are attacked they should immediately be grazed, or cut and grazed, and if the infestation is very bad the butts of the plants should be thoroughly sprayed with one of the well-known arsenical sprays. Spraying for attacks on seed crops is not likely to be very successful, and the Entomologist at the Waite Research Institute (Dr. J. Davidson) thinks that more good can be done by growers of Lucerne seed, by very thoroughly cultivating the land in the winter when the pupae are in the ground, and so considerably reduce the numbers in the first brood. When the first brood is noticed the crop should be heavily stacked, after which few will be left to produce another brood to damage the seed crop.

DODDER (*Cuscuta trifoliū*).

In some portions of the world a series of leafless parasitic plants, known as Didders, are very plentiful, and do much damage to a number of the cultivated crops. Of these, the Clover Dodder is one of the worst, and is one of the most pernicious pests with which Clovers and Lucerne have to contend. This parasite has long wire-like leafless stems of an orange to reddish color, which attach themselves to the stems of the host plants by

small suckers, and through these attachments draw all of their sustenance. The seeds, which are of a yellowish-brown color and very small (about one-twenty-fifth of an inch in diameter), germinate in the soil, and the resulting thread-like growth entwines itself around a host plant, produces a few suckers, and then the bottom of the stem dies and withers away, leaving the

CLOVER DODDER.—Showing how *Cuscuta trifolii* entwines itself about the attacked plants and eventually kills them. Dodder in full flower.

Dodder plant quite separated from the soil. The plants grow very rapidly, entwining themselves all over the host plant, then extend to neighboring plants, and soon cover fairly considerable patches of crop. The flowers, which are plentiful along the stems, and of a creamy to almost golden color, produce a lot of seeds, which fall to the ground and increase the infestation. Tiny little fragments of stems will grow if they reach the soil, and this is another serious means of spreading the trouble.

As the main source of infection comes from seed, great care should be taken to make quite certain that Lucerne seed containing Dodder is not sown. The seed is readily recognisable, and being so much smaller than the Lucerne seed can easily be removed by sieving. If Dodder appears in a crop the affected plants should be carefully cut right down to the crowns and be burnt on the spot where they grew, or if to be carted off, should be placed in bags or some such receptacle, making sure that no small pieces are dropped on to unaffected parts of the crop. Affected crops

should not be grazed by livestock, because the seeds pass through the animals unaltered and may spread the parasite. Dodder can be killed by sprays, and one of the best for the purpose is a solution of Sulphate of Iron in water, of a strength of 10 to 15 per cent. This will burn the growth of the Lucerne, but the plants will all shoot again without loss of vigor.

SUMMARY.

1. Lucerne flourishes in semi-arid climates, and although it requires much water for maximum development, it grows well wherever cereals are profitably grown in such climatic conditions. It is an important crop in South Australia now, still, on the experience of other countries with similar climate, it will become of more consequence to us in the future.

2. Lucerne has been domesticated for many centuries, and as a consequence is well known in most agricultural countries of the world. It was introduced into Australia shortly after the first settlement by white man, and has made steady progress since that time.

3. True Lucerne (*Medicago sativa*) is a fairly erect perennial leguminous plant, the stems of which originate from a crown at the summit of the taproot, situated at the surface of the ground. The leaves consist of three more or less wedge-shaped leaflets; the flowers are always violet; and the seedpods are spirally twisted in two to four loose coils, open through the centre.

4. There are numerous varieties of Lucerne, but they are often grouped together and given locality names. Those of importance to South Australia are Australian, Common American, Hairy Peruvian, Smooth Peruvian, and Arabian.

5. In suitable climates Lucerne can be grown in all types of soil between light sands and heavy clays, but it does best in rich, deep, well-drained soils containing plenty of lime.

6. The most favorable climates for Lucerne growing are the semi-arid and the sub-tropical. Very heavy yields are secured in most places where the winters are mild. The climate of all parts of South Australia is suitable for Lucerne.

7. When maximum growth is being made, Lucerne requires a plentiful supply of water, either under irrigation, from a close watertable, or from rain. On the other hand, it can make a wonderful bulk of growth on a comparatively small amount of water.

8. To ensure a good stand, only the very best seed should be used.

9. It is so important that a good stand be established during the year of seeding the land to Lucerne, that very thorough preparation is well warranted.

10. The ideal seedbed for Lucerne consists of fine soil, almost free of clods, about 1½ in. in depth, resting on very compact under-layers. On light soils liable to drift, a cereal crop should be grown on the land the year previous to establishing the Lucerne, and the seed be drilled into the stubble.

11. Drilling the seed into the land is the best method of seeding, provided it is not put in to too great a depth.

12. In most conditions in this State it is better to seed the Lucerne in the autumn rather than in the spring.

13. For long-time stands under irrigation, 20lbs. of seed per acre should be used, but if not to be irrigated, 10lbs. to 15lbs. are sufficient. On sandy

land over a fairly close watertable, from 9lbs. to 12lbs. are sufficient. On ordinary wheat lands from 6lbs. to 8lbs. are enough; and on sandy wheat lands of the mallee, from 4lbs. to 6lbs. are ample.

14. "Nurse" crops are never required for Lucerne in this country unless being seeded on bare, sandy land liable to drift, and then about 15lbs. of barley or 20lbs. of wheat are an ample seeding.

15. Fortunately it has not yet been found necessary to inoculate the land for our Lucerne crops, but when some sour soils are being seeded to the crop we may have to do so.

16. Unless farmyard manure is well rotted it should not be applied to the land at seeding time. Depending on the conditions, from $\frac{1}{2}$ cwt. to 2cwt. superphosphate per acre is the only fertiliser required at this time.

17. If the soil is deficient in lime, a dressing of about 2 tons per acre should be applied before seeding to Lucerne.

18. Autumn-sown Lucerne needs no after-seeding treatment except to cut weeds once in the spring, whereas when spring-sown it may be necessary to cut the weeds two or three times.

19. When Lucerne is grown on heavy-textured land, the soil should be cultivated very thoroughly at least once each year. Light-textured lucerne land does not need the same cultivation, but plenty of harrowing does much good.

20. All forms of farmyard manure stimulate Lucerne crops, and an annual application of superphosphate should be applied at cultivating time.

21. Lucerne is almost an ideal crop for cutting and carting to livestock, and is also suitable for grazing. The life of the stand is considerably shortened, and each growth during the year is retarded by grazing instead of cutting.

22. If a first-year stand of Lucerne is thin, the weak patches should be reseeded while the plants are young, otherwise it is almost impossible to thicken-up the stand.

23. To re-establish a stand, the land should be very thoroughly ploughed, and two non-leguminous crops be grown on it before reseeding to Lucerne.

24. Lucerne reaches its maximum development when grown in semi-arid climates with irrigation.

25. When plenty of water is available, flooding is the most economical method of irrigating Lucerne. If the supply of water is rather limited, it should be run in between rows of plants. When only a small amount of water can be used, or when the difficulties of grading are considerable, the water should be applied from overhead sprinklers.

26. More or less expensive soil levelling is usually necessary before establishing Lucerne that is to be irrigated, and as the grades and levels are expected to last for many years, the job must be carried out properly.

27. Before seeding to Lucerne in irrigated areas the land should be thoroughly watered, and the seed should be put in while there is still enough moisture in the soil to ensure a full germination.

28. The amount of water available controls the details of water application. If maximum results for available water are being sought the water must be made to cover as large an area as possible.

29. To get maximum returns from Lucerne, water should be applied as soon and as often as the plants show that they need it. In the early part of the season one watering for each cutting is sufficient, but later on when temperatures increase one watering before and one after each cutting will be required in all porous soils.

30. Irrigations should be given as soon after cutting as possible, because the job is easier to carry out at that time.

31. When plenty of water is available the irrigating should be by flooding; on sandy lands and those liable to wash, where the flow of water is rather small, and where the slope of the land is more or less steep, the watering should be done by overhead sprinkling; furrow irrigation should be practised on soils which set very hard when dry, where there is rather a small head of water, where the land slopes a little too much for check-banks, and where soils are liable to "wash."

32. Lucerne produces very heavy crops of fine-textured forage, extremely rich in protein, lime, and minerals, suitable for and relished by all farm livestock, but particularly fitted for the production of milk and eggs, and for young growing animals.

33. Lucerne is the best plant yet introduced into this State for the production of green forage, which can either be grazed off by livestock or be cut and carted to the animals.

34. When about to be grazed by cattle or sheep, the animals should be gradually accustomed to the pasture, and should not be allowed on it when the crop is wet with dew or rain. Pigs make better use of grain, when grazed on Lucerne, and the mixture produces the best quality pork.

35. For maximum returns all heavy luxuriant stands of Lucerne should be cut and carted to the livestock. Under this method of handling the stands last for longer periods than if grazed.

36. The Lucerne crop should be cut for hay when the fresh shoots have started from the crowns, which is usually at the time when about one-tenth of the flowers have bloomed.

37. The leaves of the plant have much higher feeding value than the stems, so great care must be shown when making hay to save all the leaves.

38. Cutting the crop for hay in an early stage each time leads to the production of more forage, but shortens the life of the stand.

39. The crop should not be cut for hay while wet with dew or rain. If cut in the morning it should be in windrows or cocks by night. If cut in the late afternoon it should be in rows or cocks before cutting time next day.

40. After cutting, the forage should only be left in the swath long enough to wilt, then it should be put in windrows, and when it has toughened it should be put in small cocks. As soon as it has dried to the extent that moisture cannot be squeezed from it when a handful is tightly twisted, it should be stacked.

41. If Lucerne hay is grown for sale, or if it has to be carted long distances, it is often an economical way to handle it to press it into bales in the field where grown.

42. Cattle and sheep can be fed wholly on Lucerne hay, but with horses, pigs, and poultry it should only form portion of the ration.

43. Lucerne makes extremely good ensilage, but it is usually stored in this manner only when it is the principal forage grown, and when succulent feed is required in the winter.

44. Success in ensilage-making depends on putting the cut fodder into the silo or stack whilst quite fresh, filling the receptacle or completing the stack really quickly, and weighting it down immediately the last load is put in position.

45. The ideal conditions for the production of high-class Lucerne seed are to be found where the plants make fairly vigorous growth without

artificial watering, and plenty of sunshine and hot dry weather are experienced in the summer.

46. Thin stands of Lucerne, with the plants having all parts exposed to light and air, are the best seed producers.

47. Lucerne seed can be harvested with—(1) reaper-thresher with special mouthpiece and sieves; (2) stripper and winnower, and continually passing the unthreshed pods into the drum of the travelling stripper; (3) cutting with binder or mower, drying and threshing; (4) cutting with scythe, drying, threshing with flail, winnowing with wind, and cleaning with hand sieves.

48. There are only three pests of Lucerne of economic importance in South Australia, namely, Lucerne Flea, Boll Worm, and Dodder.

49. The Lucerne Flea does damage to Lucerne left standing for the winter, and the first growth in the early spring. Affected crops should immediately be cut or fed down rapidly, and if it is desired to keep the next growth free from the insects the stand should be sprayed with about 80galls. per acre of a mixture of 10lbs. arsenate of lead, 2qts. of nicotine sulphate, and 500galls. water.

50. The Boll Worm does damage to Lucerne crops when it attacks the seed crop. The best method of control is to thoroughly cultivate the land in winter and when the first brood appears the crop should be heavily stocked.

51. Clover Dodder is a parasitic plant which smothers Lucerne plants. Care should be taken to see that Lucerne seed is free from Dodder seed. If patches of a crop are attacked they should be sprayed with a 10 to 15 per cent. solution of sulphate of iron in water.

Fruit in store needs examination at intervals.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on April 29th, there being present Messrs. F. Coleman (Chair), H. N. Wicks (Vice-Chairman), S. Shepherd, A. M. Dawkins, P. H. Jones, A. J. Cooke, P. J. Baily, Dr. A. E. V. Richardson (Director Waite Agricultural Research Institute), W. R. Birks (Principal Roseworthy Agricultural College), and H. C. Pritchard (General Secretary).

Apologies were received from Messrs. H. S. Taylor, A. L. McEwin, and Professor A. J. Perkins.

Charges for Handling Wool.—The Conference of Yorke Peninsula Branches resolved—"That this Conference protests against the high charges for handling wool at Port Adelaide by wool brokers." The Board gave careful consideration to this matter, when it was agreed that the prices at present charged by brokers were not unreasonable.

Agricultural Statistics.—The Yorke Peninsula Conference also resolved—"That this Conference suggests that in view of the difficulty which the farmer has in obtaining authentic information regarding the world's production of his products, we suggest that the Agricultural Bureau establishes, in conjunction with other countries if possible, an international bulletin to be published every three months." To give effect to this resolution would mean the establishment of a sub-department, and the Board was not prepared to recommend action on these lines. Discussing the resolution, Dr. Richardson said that reliable information was published in the commercial columns of the daily paper, and once each month a statement appeared giving details of the world's position of wheat. He further suggested that reports should be obtained from the Liverpool wheat markets, from which extracts could be made and published in the *Journal*. Referring to overseas prices for dairy produce, Mr. Cooke mentioned that the Secretary might communicate with the Federal Department of Markets and Migration, from whom details of prices could be obtained.

Leave of Absence.—Mr. R. H. Martin intimated that he proposed making a business trip to Great Britain, and applied for leave of absence until June 30th, 1931. The Secretary was instructed to bring this matter under the notice of the Minister, recommending approval.

Winter School for Farmers.—Mr. Birks informed the Board that the Roseworthy College would not hold a Winter School for Farmers this year.

Life Member.—The name of Mr. F. Rowley, of the Lenswood and Forest Range Branch, was added to the roll of life members of the Agricultural Bureau.

Other business was considered by the Board in committee.

New Members.—The following names were added to the rolls of existing Branches:—Mount Gambier—R. J. Cleve; Ashbourne—G. Kirkham, W. J. D. Whittam, W. Carter, A. Carter, O. Watson, K. M. Horwood, W. Clarke, R. Bailey, C. J. Pitt, G. Allingame, T. C. Allingame; Wasleys—J. H. Course; Port Elliot—A. E. Hawke; Collie—A. E. Leopold; Parilla—R. M. Neindorf; Wasleys—K. Mitchell; Waddikee Rocks—E. J. Joyce, H. A. Joyce, R. W. Wilsdon; Goode Women's—Mrs. H. Smith; Hartley—L. Jaensch; Miltalie—E. J. Ramsey; Pygery—A. Riggall; Boors Plains—M. Longmire; Rendelsham—A. Adamson; Murray Bridge—W. D. Netherwood; Kalangadoo—H. Morris; Milang—Alex. Moar, B. Casley; Parrakie Women's—Miss Lorna Hagel; Belalie Women's—Miss P. Moore; Ashbourne—F. Allingame, R. D. Meyer, O. C. Kirkham, G. D. Whittam, J. Watson, H. H. Pitt; Palalie—Leslie Mayhew; Wandearah—N. B. Ferme, R. Kimberley; Everard East—Keith Wilkin; Nantawarra—Murray Dixon, Victor Herbert, Ray Forrest.

Number of new members, 45; number of members, 8,462; number of Branches, 305.

DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co., LIMITED, reported on May 1st, 1931:—

BUTTER.—The production of butter throughout South Australia steadily declined during April, but this is usual, and the importation of quantities from the Eastern States was necessary to augment supplies. The position now is, however, that there is almost sufficient cream and butter arriving for all local needs, as the purchasing power of the public generally has so much decreased. Values showed slight fluctuation during the month, and at date are as follows:—Choiceest creamery fresh butter, in bulk, 1s. 5½d.; prints and delivery extra; second and third grades, 1s. 3½d. (these prices are subject to the stabilization levies); best separators, 1s. 3d. to 1s. 4d.; well-conditioned store and collectors, 1s. to 1s. 1d.

EGGS.—These also show a seasonal decline, and each week there was a noticeable shrinkage. Supplies of cold stored are being drawn on by many holders, so that this is resulting in all demands being met. Values have firmed, and at present are:—Ordinary country eggs, fresh hen 1s. per dozen, duck 1s. 1d. per dozen; selected, tested, and infertile higher.

CHEESE.—The production with the South-Eastern factories steadily declined, but there was sufficient coming forward each week for local requirements and a small surplus was shipped to Western Australia from time to time. Values are steady. New makes, large to loaf, 7½d. to 8½d. per lb.; semi-matured and matured, 10d. to 11d. per lb.

ALMONDS.—Very heavy supplies were marketed by growers in various parts of the State, and for the time being there was a very poor demand. Towards the latter end, however, local buyers operated freely, and also some shipments were made to the Eastern States, so that stocks were considerably reduced. There has been a better call for kernels and prices are firm. Brandis, 6d. to 6½d.; mixed softshells, 5d. to 5½d.; hardshells, 3d. to 3½d.; kernels, 1s. 4½d. to 1s. 5d. per lb.

HONEY.—This commodity, which is essentially a winter food, met with better request, but with the heavy carry-over of stocks from the previous year, there were ample supplies for all needs, and rates were unchanged. Prime clear extracted in liquid condition, 3½d. to 3½d.; best quality candied lots, 2½d. to 3½d. per lb.; second grade, 1½d. to 2d. per lb.

BEESEWAX.—In good supply; demand steady. Rates nominally 1s. 3d. to 1s. 4d. per lb. according to sample.

BACON.—The demand for bacon has shown a marked improvement, which is usual with the incoming of winter conditions, and with values at so reasonable a level, the public are purchasing proportionately more extensively than usual. Best local sides, 9d. to 9½d.; best local factory cured middles, 9d. to 9½d.; large, 8½d.; local rolls, 7d. to 7½d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 1d.; local hams, 11d. to 1s.; cooked, 1s. 2d. "Sugar Cane" brand lard in packets, 11d.; in bulk, 10d. per lb.; local prints, 10d. per lb.

LIVE POULTRY.—Throughout the month extensive quantities of all classes of live poultry were marketed and cleared. Poulterers and produce dealers this year, however, are not carrying any stocks in cold store, and are buying hand to mouth supplies as required. The demand has been regularly maintained, and values, generally speaking, are satisfactory considering the times. We held one or two special sales of pure-bred stock, when good catalogues were submitted and readily cleared to a large attendance of buyers. We advise consigning. Crates loaned on application. Prime roosters, 3s. 8d. to 5s.; nice-conditioned cockerels, 3s. to 3s. 7d.; fair-conditioned cockerels, 2s. 3d. to 2s. 9d.; chickens lower. Heavy-weight hens, 3s. 3d. to 4s. 6d.; medium hens, 2s. 4d. to 3s.; light hens, 1s. 9d. to 2s. 3d.; couple of pens of weedy sorts lower. Geese, 4s. to 5s. Prime young Muscovy drakes, 3s. 6d. to 4s. 9d.; Muscovy ducks, 2s. 6d. to 3s. 4d. Ordinary ducks, 1s. 8d. to 2s. 3d.; ducklings lower. Turkeys, good to prime condition, 8½d. to 10d. per lb. live weight; ditto, fair condition, 7d. to 8d. per lb. live weight; fattening sorts lower. Pigeons, 3½d. to 4½d. each.

POTATOES.—Local, 5s. to 5s. 6d. per cwt.

ONIONS.—Brown, 5s. 6d. per cwt.

• No report received during the month of April.

† Held over.

x In recess.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

REPORTS OF BUREAU MEETINGS WOMEN'S BRANCHES.

PARILLA (Average annual rainfall, 13.95in.).

April 15th.—Present : 14 members.

HOUSEHOLD HINTS.—The following useful household hints were brought forward :—(1) When frying potatoes and it is desired to keep them from mashing in the pan, slice them as usual and then sprinkle with vinegar. (2) An economical way to clean windows and mirrors is the use of wet newspapers made into a pad, then polish with dry soft newspapers made into a pad. (3) Be sure that the teapot is thoroughly clean inside ; once a week scald same out with boiling water and soda. (4) If tea towels leave fluff on china, pass them through a weak solution of starch water. (5) If boiling water is poured over potatoes which are to be baked, they will not take so long to cook. (6) Pastry that is to be served cold should be mixed with milk, which will keep it short and crisp. (7) Minced meat mould.—A good way of using up cold meat—Mince up pieces of cooked meat, season to taste with nutmeg, pepper, and salt, break into this an egg and add about three-quarters of a cup of milk, beat all together, put into basin or mould and steam three-quarters of an hour. (8) To cut new bread, dip the knife in hot water. (9) Cooking greens.—A small piece of butter added to the water will prevent them boiling over and also prevent odours filling the room. (10) One teaspoon of salt added to the water when boiling eggs will prevent cracking. (11) Sheets of newspaper threaded with string and hung in a handy place in kitchen are useful. (12) Lemon rind rubbed on white wood such as bread-boards, &c., makes them white as snow. (13) Add a little vinegar to the water in which eggs are to be poached, and they will not spread.

PARRAKIE (Average annual rainfall, 14.52in.).

March 24th.—Present : 13 members, three visitors.

CURING MEAT.—Mrs. Beelitz read the following paper :—"The most important part of curing meat is to have a clean and good barrel or earthenware jar. *Curing Tongue.*—Throw a handful of salt over the tongue, seeing that it is sprinkled on both sides, and let it remain to drain until the following day, make a pickle of one-half tablespoonful saltpetre, one tablespoonful plain salt, and one tablespoonful of coarse sugar. Rub this mixture well into the tongue every day for a week, it will then be found necessary to add another tablespoonful of salt ; in four more days the tongue will be cured sufficiently. Sometimes the tongue is merely left in the brine and turned daily ; this method will be found to occupy a month or five weeks before the tongue is cured. *Mutton Hams.*—Choose fat, sound, mutton ; rub the hams with a mixture of sugar, pepper, and saltpetre, allowing 4ozs. of the former and 1oz. each of the two latter to every 12lbs., and 1½lbs. salt to the same quantity. After the meat is thoroughly rubbed, cover it with salt, and turn and beat it every day. At the end of a week add one teacupful of vinegar to the brine,

and continue turning and beating. After three weeks, take it from the brine, wash with fresh water, then with strong vinegar, and hang in a cool cellar for a week or less, according to the weather. It should be soaked in cold water about one hour before boiling. (2) Three gallons soft water, 1lb. coarse sugar, 3lbs. of common salt; boil and remove scum, and, when cold, pour over the meat. In two or three weeks the meat will be excellent for baking or boiling. It may be smoked if preferred. *Ham and Bacon*.—As soon as the animal heat has disappeared, salt with plenty of the purest salt and about 4oz. saltpetre to 100lbs. meat (pork). As soon as the meat is salted to taste, which will generally be in about five weeks, take it out, and if any of it has been covered with brine, let it drain a little, then take black pepper, finely ground, and dust all over as much as will stick, then hang it up in a clean, dry, airy place. (2) Dissolve salt in cold water until it will float an egg; then for 12lbs. of ham add 1oz. saltpetre dissolved in water, and add it to the brine as you pour it on the meat. Have a skewer made of iron a few inches long, sharp at one end, with a hole in it large enough to pass stout twine through; with it put strings in the leg end of hams before putting in the brine, then pack tight in the cask, with the string end up. They will be ready to smoke in six weeks, but standing longer will do no harm. Have them smoked and hung in a cool place. A smoke-house should be dark, and the smoke so supplied as not to heat the meat." (Secretary, Mrs. M. Cabot.)

PINNAROO (Average annual rainfall, 14.70in.).

April 10th.—Present: 11 members.

BEEKEEPING.—Mrs. Phillis read the following paper:—"In this paper I propose to tell in a simple way how to keep a couple of hives of bees, so that there will always be a supply of fresh honey for home use. Obtain a clean petrolecase, take one side off, and nail up what was the top of the case, then by means of a cleat allow about 4in., so that the bees can pass comfortably in and out. This opening should not be too large, because of the danger of moths getting in. The case is then stood on a table or piece of board wider all round than the box, thus forming the bottom. It is a good plan to have the hive set up on a stand so that the legs of the stand can be stood in tins. These should be kept filled with water to keep ants from getting into the hive and, at the same time, provide the bees with water. In good seasons, when there is an abundance of flowers, honey can be taken from about four to six weeks after the swarm has been boxed. Do this early in the morning, when all workers are away gathering supplies. Also it is cooler, and the comb can be handled more easily than when it is softened by the heat of the day. A smoker is used so that a little smoke can be puffed in to move any bees that may be clinging to the honey that is to be taken out, it is then easily removed without injury to the bees or the comb. Straining the honey is the next job. Apiarists use an extractor, but for small lots, 1yd. of cheesecloth will be quite satisfactory. Break up the comb by mashing with a big spoon or knife so that all the honey cells are broken, hang up in a cool place, and allow it to drain into a large dish or preserving pan, and in a short time clear honey will be ready to put in the jars. The wax must not be wasted. Empty it into an old saucepan or other convenient vessel with some water, and put it over the fire to melt, skimming off any dark or waste matter. When cold and set the beeswax can be used for many jobs. There is always a good price offering in the market should there be more than required for home use." (Secretary, Mrs. F. Atze.)

FRUIT PRESERVING.

During the course of an address on "Home Preserving of Fruit" to members of the Wilkawatt and Parrakie (Women's) Branches, Mr. J. B. Harris (Horticultural Instructor) referred to the ripening periods of various fruits which were recommended for the process. A list of fruits has been compiled from records at the Blackwood Experiment Orchard, and Mr. Harris points out that fruits in the Murray Valley would probably ripen about a week ahead of the following dates, which correspond with the time when the first picking for market takes place:—*Cherries*—Waterloo and Florence, December 1st to 8th. *Apricots*—Moorpark, January 4th to 10th; Tilton, December 30th to January 4th. *Plums*—Greengage, January 24th to 30th; Angelina Burdett, January 10th to 18th; Coe's Golden Drop, February 17th to 21st. *Pears*—Duchess, January 31st to February 12th; Peckham's Triumph, February 22nd to 28th. *Peaches*—Fuller's Cling, March 20th to 25th; Goodman's Choice, March 3rd to 7th; Golden Queen, March 2nd to 5th; Elberta (freestone), January 29th to February 5th; Salwey (freestone), March 7th to 14th.

SOUTH-EAST DISTRICT.

KYBYBOLITE (Average annual rainfall, 22in.).

At a meeting held on September 2nd, attended by 16 members, Mr. F. Martin read the following paper, entitled "Dairying for the Beginner":—*Buildings and Locality.*—Pick a well drained spot, if possible, and lay out the yards and sheds for quick handling of stock and foodstuffs. I personally favor milking while cows are feeding. In building the shed, do not stint room for the feeding race. The quickest way of handling chaff is in two kerosene tins, one in each hand, and there should be room to walk down the race with them. Have the piggery and calf pens and runs as handy as possible, or else there is a certain amount of neglect when in a hurry. Have the paddocks arranged so that dry stock can come after milkers to clear up hay, for there is always a certain amount of waste with a milking herd. Subdivide as much as possible; subdivision and rotational grazing are one of the surest ways to success. Avoid races, but if unavoidable make them a chain wide. See that you have an abundant supply of water. On cheap land, every effort should be made to plant breakwinds. Have shady trees for hot weather. A good straw shed is an asset. I do not favor bedding cows down at night. The cost of handling does not warrant it where there is plenty of shelter, and it causes bad udders.

Building up the Herds.—Good dairy cows are scarce and expensive. The saleyards mostly contain culls, and if one cannot buy direct from reputable dairymen, I prefer buying yearlings of good dairy type of the favored breed, or heifers in calf or springing. If heifers turn out duds, one can get out without much loss, whereas there is considerable loss on cows at, say, £15 a head. When looking a cow over with view to purchase, first get behind and see that she is broad across the pins, and well let up towards the tail, with udder coming well up. She should be well defined and strong looking at the hindquarters. I do not like a round, heavy-looking beast from this view. From side view, see that her udder runs well forward, and that there are no traces of a lopsided or lumpy udder. I like to see a cow long from the point of the hip to the pin bone, especially so in bulls, it generally means good uddered stock. Avoid tight-chested and narrow-gutted cows, they are generally poor producers, and more subject to bloat than the deep ones. Avoid narrow-headed, pig-eyed cows, they are generally bad tempered, and poor producers.

In general appearance the cow should be strong, well defined, yet fairly fine. Often rather heavy pointed heifers milk the heaviness off after a month or so. She should look a bundle of energy, showing good nervous system, with a good network of veins underneath. Avoid heavy, sluggish, tight-skinned beasts. The bull should be the best one can afford to buy, backed by a good butterfat record. See that he is kept in a yard or good paddock. If in a yard, he needs a run every little while. *Breed.*—Any of the light breeds should be suitable for most of the South-East. I prefer Ayrshires. I do not favor heavy and so-called dual purpose breeds. The only advantage of these is a better calf and carcass when the cow is finished, but bear in mind her maintenance is far greater; 60 per cent. of food consumed goes in maintenance. *Growth of Cows from Calves.*—When the cow is due to calve, bring her into a field handy for observation. Do not worry her while calving. Leave the calf with her for 24 hours, ease her udder a little, but do not be in a hurry to milk her right out, as it may cause milk fever. Should she go down with milk fever, take her calf away immediately. Only under exceptional circumstances milk her before calving. The calf should be fed on 1 gall. of fresh milk for three or four weeks, and then gradually brought on to skim milk with addition of boiled linseed. I have not much faith in calf foods, they are too expensive. Keep them away from solid foods for two weeks, then give a little crushed oats or good hay, and the run of a good paddock. I prefer feeding calves in small bails; they do not forget it when coming into milk. Dehorn all calves you intend keeping. See that the paddocks are well fenced, for once they start the crawling habit, you will never break them of it. Keep them in good growing condition, but do not get them too fat. A heifer should be mated at about 18 months, if well forward she may be put to the bull earlier. When a heifer has calved, handle her gently. Avoid the use of a leg rope if possible. When necessary, use a figure 8 around the hocks, or place the leg rope high up. A very important point is to keep them in milk until six weeks from calving, letting a heifer dry off three or four months before calving is ruination; they acquire the habit, and you cannot break them of it. I believe there is a good deal in favor of bringing all the cows in as near as possible at the same time; it gives one a well-deserved rest, and allows you time to have the plant overhauled, etc. No one can foretell the price of butterfat for any period ahead, so one must aim at bringing cows in at such time that they will get the most milk possible over a lactation period at a minimum cost. To my mind the best time is two or three months before there is a good bite of grass in the paddocks. Under these conditions they have not gone stale by the spring, and will be flush again with the bulk of food, whereas if they have been in milk four or five months, they do not show much appreciable increase. Feed the dry stock through winter. If a cow calves in the spring, she gets about three months of good cheap feed, and then hand feeding must be resorted to. It is far more expensive to keep a cow going after the flush of feed than two or three months before. With winter dairying, the cows have all calved and settled down by shearing, and the calves do not need so much attention. With spring cows a good deal of trouble will be experienced right at the busy time. By harvest, the winter cows are easing off in the milk flow, and by seeding and manuring time, they are only just starting to come in, so that you have the busiest time with cows when other work is not so pressing. Generally under these conditions, pigs can be marketed before they drop in price, as they usually do about November. The calves of the winter drop do far better than those of the spring drop, and most of the cream will have been disposed of before hot weather sets in. Very hot weather is trying to a cow with a large flow of milk. *Feeding.*—During autumn and winter I feed a cow on about 2 lbs. of concentrates with a little chaff for a week or so before calving. It has been my experience that they milk all the better for it. Always bring in the cows in good condition; if poor, it takes a lot of feed and a lot of butterfat is lost before she gets into good working order, for, bear in mind, she is a reproducing machine, producing butter from foods consumed. I do not believe in feeding fair average cows on more than 5 lbs. of concentrates per day. The latter should be given with chaff hay. It is a good plan to give cows a little dry chaff, and perhaps 1 lb. of crushed oats right through the spring; cows often look for dry, solid feed when other feed is sappy and green, it tends also to reduce the bloat. In a district with a bulk of good spring grass, good clover hay and ensilage are the most economical foods to handle. With the aid of the push rake and stacker, ensilage is not an expensive food; a silage crop yields six or seven times the amount of hay per acre, it is there for ever, and you are always sure of a plentiful supply of good, succulent food when wanted, whereas with the growing of summer crops, too much depends on rain, and it is doubtful whether they will yield as much fodder per acre. Summer crops are expensive to handle, and with winter dairying there is not so much necessity for them. Should one be fortunate to have a good supply of irrigating water, it is best to sow down pastures, irrigate, and let the cows do the rest. When spring is well advanced, do not wait until the cows drop considerably before you start feeding; feeding at this time of the year only has the effect of keeping up the flow of milk, and dairymen are inclined to think it unprofitable to feed because there does not appear any apparent gain. Try the experiment yourself. Take two or three cows, and start feeding on a little concentrate with silage as soon as they start to go off, and compare them with the others in three or four weeks' time; the results will surprise you. Once the cow's supply has dropped considerably, it is waste of money trying to get her back. Always try to shut up a few acres in winter for early feed. I mentioned previously rotation grazing. This entails fencing into about five-acre fields for a herd of about 35 cows. A fence I have found very effective is three plain wires and two barbs on top. Graze the fields in rotation, and keep

growth down to about 4in. Cows do far better on short feed, the carrying capacity per acre is greatly increased, and it allows for the shutting of up paddocks for hay. These short-grazed paddocks make excellent fields for sheep. They remain green a little longer, and the system pays handsomely. Once grasses have dried off, they are useless from a production point of view, but they are good fields for dry stock and for fattening. *Milking Machines.*—There is a good deal to be said in favor of milking machines where there are over 10 cows per milker. They are an economic necessity. One man can handle comfortably a two unit plant, which should milk 14 to 16 cows an hour. I especially like the bucket type, which can be used in the feeding shed. From the point of view of sanitation, they are equal to, and perhaps better than, hand milking. Where they are neglected, they are a curse. They require a fair amount of attention, and certainly take longer to clean up, but given reasonable care and intelligent handling, they are in no way injurious. I have seen cows with out teats that were painful to milk by hand, stand quiet when the machines were put on. While on the cows, they should be closely watched, and taken off as soon as the milk tube on the claw cools off. Leaving on too long, is one of the main causes for cows holding their milk. I do not think it pays to put the machines on a cow when giving less than 5lbs. at a milking. I am inclined to think that you get more milk over a lactation period from good hand milking than machines. Machines need steaming, or else putting in limewater or a weak formalin solution between milkings. A good class of steamer for machines and milking utensils and separator parts is to have a copper, put in a little water, then let in a netting tray above the water, put in buckets, &c., after being washed, cover them over, and let them steam for a time. Always take the separator bowl to pieces and clean it after every milking. *Washing Cows' Teats.*—This does not seem much, but is the most neglected part of the cleanliness in a dairy; too many just wet them and allow the hands or machines to do the rest of the cleaning. They should be thoroughly washed and dried. Always use a weak Condy's solution; see that the rag used for washing is thoroughly cleaned and aired. Always squirt the first couple of testfuls of milk on to the floor. Keep the cream in a cool, well-aired place, and send to the factory three times a week in summer. Always remember, do not sell the other man what you would not use yourself. If all the cream produced was of good quality, there would not be the necessity for importing butter from other States. Treat the cows with gentleness, and one factor that plays an important part in success in dairying is to practically milk by the clock. Always start as near as possible at the same time daily. (Secretary, Mr. F. Martin.)

MOUNT GAMBIER (Average annual rainfall, 30.74in.).

November 14th.—Present: 10 members.

USEFUL PLANTS AND SEEDS.—Mr. A. Kipselbach read the following paper: "Carroway.—This is a plant that grows well in our district, it is a perennial that seeds very heavily. I have some two years old in my garden at present, and anyone wishing to try it I will give them seed. Hundreds of tons are imported. Linseed (or flax).—This grows well here, in fact it is a native of Mount Gambier. In the early days it could be found growing amongst the grass in many parts of the district, especially north-west from the town. The best place to grow it would be near the Dismal Swamp, where there is plenty of water so that the fibre could be used as well as the seeds. Sugar Beet.—This was tried here somewhere in the sixties, but turned out a failure, as the tonnage was too small, and as there was no chance of getting a sugar mill started here, consequently it was only used for pigs. Tantanoola and Rendelsham are more suitable for the sugar beet, which

B. Kannenberg's winning entry of Up-to-date variety in the Mt. Gambier Potato Crop Competition.

demands black, rich soil. Berries.—These ought to be grown more plentifully here. The soil and climate suits them well, especially loganberries, raspberries and strawberries. These three bear remarkably well. Silver Beet.—This is a most useful plant. It will thrive in any soil and is green all through the hottest summers. It requires no cleaning, and will grow like a weed. Simply cultivate the land and broadcast the seeds with Cape barley or oats. When the barley and beet is about four to six inches high turn stock into it or mow it off. The more it is cut the better it grows, and if kept cut and fed down it will stand for two or three years. The best time to sow it is about March or April, and again in September and October, and even into November. It is far more nourishing than chow moolie and less trouble to feed to stock. Hundreds of acres are grown in the lower North to fatten sheep.

Congress reports were received and discussed at the meeting held on October 10th, which was attended by 12 members.

Meeting held December 12th. Present: nine members. A paper, "The Blowfly Pest," was read from the *Journal* and an instructive discussion followed. (Secretary, Mr. G. Gurry.)

RENDELSHAM.

November 8th.—Present: 12 members and two visitors.

Mr. S. Smith read several extracts dealing with the cultivation of the potato. The meeting held on December 6th took the form of a "Question Box." "When is the best time to cut rye for hay?" The majority of members favored cutting on the green side. "Is fruit taken from a tree after being sprayed with arsenate of lead safe to eat?" It was thought that if it was sprayed with ordinary strength when fruit was young there would be no danger. "What color flowers have the following potatoes:—Carmen, Snowflake, and Up-to-Date?" The answer was—Carmen, white; Snowflake, blue; and Up-to-Date, purple. "Can you tell the color of the potato flower by the shoot?" Yes, they are the same color. "Do cut potatoes throw shoots from the opposite end to the crown?" It was thought advisable, where possible, to cut

the potato lengthways, in order to get part of the crown on each side, especially with Carmen and Up-to-Date. "How thick should mangel seed be sown?" About 2lbs. per acre. "What is considered the best method of supering potatoes?" Best results in this district were usually obtained by supering by hand. (Secretary, Mr. F. White.)

March 28th.—Present: 13 members, four visitors.

THE DAIRY COW.—The following paper was read by Mr. C. Faehrmann:—"Many farmers in this district, who were chiefly occupied in the production of wheat, owing to the falling prices in wheat, have turned their attention to dairying, and have established fodder plots and installed milking machines on their premises. Their chief reason is that cream invariably returns them regularly 'ready cash', which, in existing times, is most essential, while their wheat returns, owing to fluctuations, are so uncertain. With all the natural possibilities and suitable land available in this district, which carries an abundance of natural grasses, there is a splendid opening for an enthusiastic farmer, to establish a good dairy herd, commencing on a small scale with good sound stock, and with that end in view the following points may prove helpful to the prospective farmer in selecting a good type of cow as a nucleus for his herd. *Production Factors and Essential Characteristics of the Ideal Dairy Cow.*—To be successful in dairying a man must have many attributes, but above all he must be a good judge of dairy cows. No one can hope to tell from the appearance of a cow how much butterfat she will yield. This has been demonstrated repeatedly ever since herd testing began. The really only reliable guides are the scales (weighing) and the Babcock Milk Tester. Unfortunately, however, cows cannot always be purchased on their test records, and in purchasing new blood, or building up a herd of his own, the dairy man who has a sound knowledge of the essential points of a dairy cow will make fewer mistakes than the man who has not that knowledge. It must be borne in mind that to all intents and purposes the dairy cow is a 'machine' for the reproduction of her kind and for the production of milk and butterfat. Her commercial value depends on the quantity and quality of her production, and her ability to maintain her productiveness over extended periods. If the 'machine' is to function properly and profitably certain characteristics are essential. Among these the most important are—(1) Constitution, (2) capacity, (3) nervous temperament, (4) blood circulation, and (5) ability. Each of these characteristics enumerated are so vitally important, that it is difficult, if not impossible, to say which is most essential. Unless they are all in their proper development, profitable production cannot be expected. These essential characteristics are not confined to any particular kind (breed) of dairy cow more than another. The choice of a particular breed is only of secondary consideration and a matter of personal preference of the farmer. The important thing to ascertain is, that the cows that are selected have the above characteristics. If she is to produce satisfactory quantity and quality of milk, a cow must have 'capacity', and if she is to continue the good work throughout her lifetime, she must have a vigorous constitution and abundant vitality. Constitution in a cow is determined by a number of factors, foremost of which is 'ample breathing capacity'. Oxygen is essential for the purification of the blood, and if the cow is to receive the required amount of air, a large breathing capacity is required. This is demonstrated by a good lung capacity and large, open nostrils. If the nostrils are small and not well opened, the amount of oxygen which reaches the blood through the lungs is restricted and constitutional vigor is under-developed. Small nostrils are a definite indication of low breathing capacity. The vitality of the animal is determined partly by the size and capacity of the chest, within which are located the heart and lungs. The dairy cow should be deep in proportion to her size, from the top of the shoulder to the base of the chest. To give the vital organs ample room for development and action the fore ribs should be well sprung, but not broadened out into the widespread of the beef animal. Another indication of the vitality of a dairy cow is found in her eyes. Bright, clear, and prominent eyes are evidence of vigor, while the cow with dull, sunken eyes is usually the animal to be avoided. By capacity, is meant the total amount of feed she can consume and digest, while her profitable capacity lies in the amount of feed she can assimilate above the quantity required for her own bodily maintenance. Usually cows which are big feeders are more profitable than those of a smaller capacity, as they are less dainty in their tastes and will consume a greater proportion of the more plentiful and coarser roughages. Cows with limited capacity are more likely to go off their feed and get out of condition with the result that their milk flow also falls away. A cow must, therefore, be fed heavily if she is continually in milk. A large mouth is a matter of prime importance. A large mouth indicates a good feeder, and the best evidence of capacity is a large barrel. This is accompanied generally by length of body with broad, deep, and well sprung ribs, and a large girth measurement in proportion to the size of the animal. Breadth and depth of body are more desirable than length. Lengthy bodies without the well sprung ribs indicate generally a poor feeder, a poor producer, and a poor mother. The condition of the hair and skin must next be taken into consideration. The cow with a hide that is soft and pliable, easily lifted from the body, and covered with a soft silky coat of hair is in good condition and has her digestive apparatus in proper working order. Dull eyes, harsh skin, and wiry coat are indications of digestive troubles. So far as 'Nervous temperament' is concerned, a dairy cow should have a strongly developed nervous system to enable her to carry on with milk production and her offspring. The term 'Lymphatic temperament' is essential for beef cattle. These two temperaments are contrasts. The 'Lymphatic' enables the animal

to lay on 'beef' while the 'nervous temperament' enables the dairy cow to lay on 'milk' (i.e., they may eat the same food but make different uses of it). Nervous temperament is indicated by a long, broad forehead with plenty of space between the eyes. Other indications are prominent, large and intelligent eyes. Freedom from 'beefiness', absence of surplus bodyfat, and extreme angularity of form, with prominent hip bones and ribs are also evidence of the desired nervous temperament. 'Blood circulation' is next in importance. Unless the cow has a good circulatory system she cannot derive the maximum benefit from the food consumed. The 'milk' veins which extend forward from the udder are actually blood veins, and their size, length, and form serve to determine the quantity of blood which flows through the udders. These veins terminate in the so-called 'milk wells' which are the openings in the abdominal wall where the veins re-enter the body. Usually, both the 'milk veins' and the 'milk wells' are large in heavy-producing cows. With large production the veins may be also very crooked, and have several branches, with as many milk wells. Therefore, the development of the system of milk veins is one of the best indications of milk production capacity of the cow. The fifth characteristic—the ability to produce—is not merely the capacity of the cow for milk production. She may have the capacity and yet lack the ability to produce up to that capacity. By capacity is meant that the cow can consume, digest, and make use of, or assimilate large quantities of feed; while ability means that she can turn the nutriment elements of that food into milk and butterfat. It is, perhaps, the most important of all the characteristics, for without it the others are of little avail. The size, form, and texture of the udder are practically the only indications or outward manifestations of her ability. The udder should be long and broad, attached high behind, and extending well forward. Its breadth should fill the space between the thighs, and it should have a nearly level bottom line parallel with the underline of the body. A deep pendulous udder is undesirable. Quality and texture are highly important in the udder. There is evidence of both when the vessel is soft and pliable, capable of great expansion when full, and equally great contraction when empty, and covered with a coat of silky hair. It should be well distended and smooth before milking, and should gradually collapse in numerous soft folds when the milk is withdrawn. Though the foregoing are not infallible rules, a knowledge of the essentials and characteristics outlined above are necessary for the dairy farmer who hopes to build up a first-class herd. Used sensibly and in conjunction with testing, that knowledge should provide both profit and pleasure to the owner, for there are few more occupations more interesting than the breeding of high-class livestock, and particularly dairy cows." (Secretary, Mr. F. White.)

APPILA (Average annual rainfall, 14.69in.).

November 7.—Present: 14 members.

The Hon. Secretary (Mr. E. H. Wurst) read an instructive paper, "Care of Motors on the Farm."

Meeting held February 6th. Present: Mr. G. Wurst (Chair), 10 members, and two visitors.—*Harvest Reports*.—Considering the rain that had fallen during the growing period for the past year, fair returns were reported by most members. Good fallow yielded up to 3bush. more than late fallow which had not been worked. Best yields were obtained from the following varieties:—Nabawa, Daphne, Sepoy, Golden Return, German Wonder, Waratah, Leatherhead, Sultan, and Currawa.

BLACK ROCK.—The meeting of November 4th was attended by Mr. C. Kuerschner (Chair) and 10 members. Mr. E. L. Orchard (District Agricultural Instructor) spoke on the subject, "Fodder Conservation." (Secretary, Mr. R. Kitto.)

FARM ECONOMIES.—Mr. S. Bennett read the following paper:—One has to remember that farm economies and farm activities are so closely related and dependent one on the other that it is impossible to draw any very fine distinguishing line between them. Farm activities may be carried on in such a way as to be an easy and pleasant avocation, and during the seasons of a few years past more or less satisfactory, but farm activities, coupled with the most thoughtful economy, will be essential if we are to balance the budget in the present and coming seasons. During the last few years, when crops were good and prices high on account of the world's markets being not only open to us, but purchasers were prepared to, and did, pay considerably more than prewar prices for our produce, economy of practice in our activities was allowed to drop into the background. Many farmers of to-day are simply grain growers; three years ago a profitable occupation, to-day, with the ever-increasing cost of production, the alarmingly inadequate prices offered for grain, a difficult and almost hopeless position has arisen. Farmers of to-day, generally speaking, are possessed of the most up-to-date equipment procurable. The modern farmer as a grain grower is efficient, and as a result of that efficiency is left with a great amount of spare time, very little of which is spent either profitably or economically. I use the term profitably in the sense that little (if anything) is being added to your income. Most farmers to-day grade their wheat for sowing, an undoubted economy on the old methods practised, but possibly a further economy might be realised by a more careful selection of the crops as to freedom from disease and suitability to district before the grain was brought to the grader. Harvesting machines of to-day as grain gatherers are possibly the last word in efficiency, and at the same time prodigal wasters of the by-product, wheaten chaff. In searching for economy on the farm, we are searching for a means of deriving a profit from the greatest possible amount of the crop or products raised on the farm, and to allow the wheaten chaff to waste, when it has an undoubted fodder value, particularly in the winter months, to cattle, and even milking cows, is not economy. Wheaten chaff when blown out on the ground is worth practically nothing, but when saved with the view to carrying more stock, which would be marketed, or as part of the ration of dairy cows, it would undoubtedly show a profit, and is an economy worthy of consideration. At the present price of wheat, it should be advisable to have some portion of the acreage cropped, sown to oats, which not only benefit the land, but is a fodder of exceptional value in carrying stock over those periods when there is a scarcity of natural feed. Super is a costly item, and a saving might be effected by individual farmers carefully testing the yields and profits derived from the different amounts of phosphate used. If the larger outlay necessary for a heavier dressing of super meets with a corresponding profit in the yield, it is economy to use the heavier dressing. Minor repairs to plant, harness, &c., which do not require a tradesman or expert to effect, should on no account be overlooked. It is at any time a real economy, and under present conditions a vital necessity. Water supplies on the farm should, if plentiful, do more than supply the needs of the stock carried. The farm garden and some class of fodder for summer should be cultivated to the extent that the water supply and the available labor will permit. Economy that will be profitable in our activities is to make the fullest possible use of the resources of and what is grown on the farm by such sidelines as stock, dairy cows, pigs, and poultry. It means time and work; modern equipment has given the farmer the time, the farmer must give the work. The sidelines mentioned above fed on the produce raised on the farm will not prove easy money, but they may in some measure solve the difficulties with which the farmer is at present faced. (Secretary, Mr. R. Wilkinson.)

EVERARD EAST.**November 8th.—Present: Seven members.**

CURING MEAT.—Mr. F. Hughes read a paper on this subject:—“In the successful pickling of meat a great deal depends on the killing of the animal. If it is rushed about, overheated, and excited, it will not bleed thoroughly, which is very much against the appearance of the meat and is a handicap in the curing if the weather is a bit warm. If killing a sheep, it should be penned either the night before or the morning of the day it is to be killed. If killing beef and the place of hanging has not a small yard around it, I would recommend tying up the animal in the morning, then in the evening it can be shot before sticking, thus ensuring a good bleed and cool, clean meat. As pigs are generally killed in the winter, it is not so necessary to be quiet, but it is an advantage not to feed the day you intend to kill. Shoot the animal and stick in the sty so as not to overheat or excite it, and you will have the

3 Harrows in One for the Price of One

The Whakatane Harrow is an all-purpose implement designed in such a way that three exceedingly efficient working surfaces can be secured from the one set of harrows. On the one side a long tine cultivation is provided for, on the other, when drawn one way, the harrow becomes a first-class tripod, and when drawn the other way, as shown in the accompanying illustrations, a manure-spreading, seed-covering harrow, which many skilled farmers and agricultural experts claim as being the finest manure spreading effect so far made possible with harrows. The Whakatane is designed to treat all classes of country and to suit different types of farming—wheat areas, dairying and mixed farming—being particularly suited for the renovating of pastures and the preparation of seed beds. Its principle of "three harrows in one" gives it an extremely wide scope of usefulness and renders it superior to any of its kind.

meat in the best condition for curing. I favor brine or wet pickle; it is not quite so much work, and if properly done, there is not so much chance (if any) of oversalting. To make a good brine, thoroughly dissolve enough salt in the water to float an egg, which should not be more than one day old. A stale egg will float in a good deal less salt and you run the risk of not having enough salt to cure the meat. If you cannot get a fresh egg, a good potato will do, but it floats sooner than a day old egg. After having floated the egg, add some saltpetre—two or three cupfuls to 100lbs. meat in good weather, twice as much if the weather is a bit doubtful. Saltpetre is used chiefly to color the meat, but it seems to help the salt to penetrate more quickly, so lessening the risk of loss, but hardening the meat a little. A handful or two of sugar will improve the flavor, but it is not necessary. A vinegar cask is a very good pickling vessel and should be kept in the coolest place possible. If you have plenty of water, the best place is outside under a heavily foliated tree with a good sized patch of wet ground about the cask. There are very few nights that do not cool enough to lower the temperature of the brine under these conditions. The meat should be reversed every day or two, according to the weather, for the first week, and just sufficiently weighted to keep it under water. When not in use, the cask should be kept full of water and emptied at least every two days in summer and never allowed longer than a week in winter; if allowed to become "smelly," it is almost useless for the purpose. If for some unknown reason the animal has not bled properly and the brine becomes bloody, it should be boiled and skimmed until clean, but if the method suggested has been thoroughly carried out, this should not be necessary." (Secretary, Mr. F. Hughes, Blyth.)

MOUNT BRYAN (Average annual rainfall, 16.79in.).

Mr. G. Goodridge presided over an attendance of 11 members and 19 visitors at the meeting held on November 11th, when Mr. W. J. Spafford (Deputy Director of Agriculture) delivered an address, "Improving Returns from the Farm." (Secretary, Mr. H. Edwards.)

LOWER-NORTH DISTRICT.**(ADELAIDE TO FARRELL'S FLAT.)****BLACK SPRINGS.**

November 4th.—Present: 10 members.

Debating the subject, "Horses v. Tractor," a team consisting of Messrs. Woolcott, Dixon, Turner, and Hogan, of the Hanson Branch, supported horses, whilst Messrs. Rodda, J. Howard, C. Dunn, and R. Turner, of the local Branch, spoke in favor of tractors. The local team was adjudged winners by 79½ points to 75½. On October 7th reports of delegates to Congress were received.

GREENOCK.

Thirty-seven members and several visitors attended a meeting held on September 15th. Mr. M. Laucke read a paper, "Wheat for Milling." He said that soundness was the outstanding factor in the choice of wheat for milling purposes. Regardless of any points of quality which a wheat might possess, such as high test, weight per bushel, or high protein content, if it was unsound, it was of no value to the miller, because he could not possibly make good sound flour from it. Generally the spoilage of wheat was due to harvesting and storing wheat which contained an excess of moisture. It made little difference whether the wheat became wet after reaping, or whether, as was sometimes the case, the excess of moisture in the wheat was due to it having been reaped before it was ripe; the results were the same. Stimulated by high moisture content in the grain, the head developed and fermentation took place, with the result that the grain spoiled. At times, largely as a result of bad weather conditions at the time of harvest, there had been some spoilt grain on the market. With some such wheat there was no doubt about its being unsound, because the odor and appearance immediately warned the miller. Some lots of wheat, especially those which, although they contained an excess of moisture, had not yet reached the state of spoiling, were not so easy to detect, and millers at first had much difficulty in determining whether grain was sound or not. Also in many cases a miller was not sure of the condition of some wheat until it had been milled and the flour therefrom made into bread. Wheat should be allowed to become properly ripe before reaping. No matter what skill a miller might possess in making flour, or what class of machinery he had in his mill, he could not satisfactorily overcome the difficulties of having to grind immature or unripe wheat. Especially should wheat be allowed to become dead ripe when such grain was to be used for seeding purposes. Exposure to the sun's rays acted as a disinfectant to wheat, and the crop grown from such seed would be much less liable to smut infection. Smut was one of the worst enemies of flour with which a miller had to contend, and should be guarded against as much as possible by wheat farmers. Much could be done to prevent smut by using for seed only pickled wheat which was fully matured and dead ripe before reaping. Only from fully matured wheat which was free from smut, barley, oats, and all foreign grain or weeds, could a miller produce a flour of good baking quality. Straw and chaff, &c., should also be eliminated as much as possible before wheat was put on the market. Although not making much difference as regards weight of wheat, straw, and chaff in large quantities caused much inconvenience to millers on account of choking and blocking in the various machines used to prepare wheat for grinding. The varieties best suited for milling purposes were wheats of a light color. Dark and hard varieties could only be used in very limited quantities for mixing with wheats of a lighter color, and therefore were not liked by millers, since such wheat required careful attention. Florence wheat was one of the hard varieties. It gave a very strong flour, and was good for mixing in the proportion of about one to seven of soft wheats, but came partly under the red varieties, because it could not be used without mixing and required careful attention by millers. If a wheat was good for mixing, but not as good as a straight white wheat, it could not be recommended, even where such wheat would beat all records in standard weight per bushel. Red wheat should not be grown by Australian farmers, because European flour millers could purchase red wheat at a lower price than they would pay for white varieties. Red wheat produced a flour out of which the European bakers made a cheaper and inferior grade of bread. Consequently the Australian farmer would have to accept a lower price for his red wheat. Wheats of the same variety might produce a flour of entirely different baking quality if grown on different classes of soil. The flour of a wheat grown on limestone country was of superior baking quality. (Secretary, Mr. H. E. Wilksch.)

: GREENOCK.

January 5th.—Present: 29 members.

CROP ROTATION.—Mr. C. Werner read the following paper:—"No one more readily realises the value of a rotation of crops than the capable market gardener who practises intense culture. It is a well known fact that a farmer in this district cannot successfully grow two cereal crops in succession on the same ground. For this reason, as well as for the purpose of conserving moisture, it is necessary to fallow and crop the land only every other year. But by continually sowing the land with wheat every alternate year the ground is inclined to become wheat sick. This proves the necessity for crop rotation. A simple form of crop rotation, and one that at one time proved to be successful, was the three-year system, *e.g.*, fallow-wheat-pasture. Owing to the high price of land and the drop in sheep and wool, this method would not be profitable at the present time. A form of crop rotation that had gained popularity in recent years was bare fallow-wheat-peas-wheat; crops were successfully grown under this system in wet years; however, the wheat crop following on peas proved to be a failure in dry seasons. A more reliable system would be fallow-wheat-peas followed by fallow were it not for the grub menace. From personal experience I select oats sown on fallow as the most profitable form of rotation. Supposing we have a farm of 600 acres of arable land of which we have 300 acres under crop annually and 300 acres under fallow, I advocate sowing 50 acres with oats and 25 acres with barley each year, selecting a different plot of 75 acres for oats each year, then in a term of eight years the whole farm would have had the benefit of an oat crop. My reasons for selecting oats are that they draw different constituents from the soil than wheat, they check weeds, and minimise disease for future wheat crops, particularly take-all, to which oats are not subject. In this respect they are most valuable on Bay of Biscay ground, with a pipe clay subsoil, which is most susceptible to take-all. On my farm I had a piece of ground badly infected with this disease. As an experiment part of this was cropped with oats, with good results, and two years later sown with wheat on fallow, which yielded a clean and heavy return, free from take-all. The crop on both sides, which did not have the benefit of a preceding oat crop, was light, full of weeds, and badly affected with take-all. Many farmers who are accustomed to feeding wheaten hay only, perhaps do not realise the food value of oaten hay. Chemical analyses and digestion trials have proved that, compared with wheaten hay, it contains from 10 per cent. to 15 per cent. more digestible nutrients, in addition to this there is some principle peculiar to the oat plant which has a stimulating effect on the animal system. For dairy cattle it is particularly valuable, as it increases the milk flow. There is no other grain food as valuable as oats for horses. I would not recommend oats as a grain food for pigs—barley being more economical; but for the purpose of stimulating the secretion of milk in cows, oats are equal to bran, especially when crushed. As regards feed for sheep, oats are far superior to other cereals when paddock feed is scarce and hand feeding has to be resorted to. Chemical analyses prove that oaten straw is far superior to wheaten straw in flesh-forming constituents. Oaten cock chaff, compared with wheaten cocky chaff, reveals the same results. From experience I would recommend Algerian and New Zealand Cape as suitable varieties for this district." The following are extracts from the discussion:—"Excellent results have been obtained after pease had been grazed off by sheep and the land cropped the following season. The usual procedure in a fallow-wheat-peas-wheat rotation is to cultivate the land for the peas and to skim-plough it for the wheat crop following the peas. It is advisable to cultivate after the ploughing in order to consolidate the soil; it was pointed out that in all late fallows it was essential to cultivate to ploughing depth for the initial cultivation in order to eliminate hollows or 'air-pockets.' The superiority of oats (over other cereals) for checking weed growth was commented on, it had been most noticeable where the land was infested with fumitory. As a crop for grazing, it was recommended to sow a mixture of barley and Algerian oats. The barley provided early feed, and, with opportune rains, the oats would provide a picking right into the summer. Farmers were warned not to sow Early Burt oats for this purpose, as it would not stool well, and, once grazed off, made a very poor recovery. In any case it was not deemed advisable to grow the above-named variety in this district. A member said he had a paddock sown with oats last year, and, as the weather in June was abnormally dry, he turned his sheep into the crop. When, at the end of the month, splendid rains fell, the paddock was apparently bare; in a surprisingly short time the oats sprouted 'as thick as a brush' and eventually yielded a good return. The variety was Algerian. It was stated that barley, as a rule, was cleaner from weeds than wheat, it was contended, however, that this was due to the fact that barley was invariably sown later than wheat, when most of the weeds had germinated and were killed by the cultivator." (Secretary, Mr. H. Wiltsch.)

OWEN.

October 29th.—Present: 15 members and 20 visitors.

FIRST AID.—The following address was given by a medical practitioner:—"Let us firstly consider the most efficient articles always useful in case of accident. Valuable as the roller bandage is, my medical experience leads me to the conclusion that the triangular bandage is the more practical. This is made by cutting a piece of linen or calico 40in. square diagonally into two pieces, and by using this type, various bandages, such as the broad, narrow, and medium, may be fashioned simply by folding to the various widths; but in all types, it is necessary to first fold a hem about an inch wide at the broad end, to facilitate tying and give greater stability. Splints will probably have to be improvised on the spot, such as pieces of kerosine case, a broom handle, walking stick, or even a newspaper rolled tightly—in fact, anything that is firm enough and long enough to keep the joints immediately above and below the fractured bone at rest. Perhaps at this stage it would also be advisable to stress the value of having on hand small quantities of lint for applying immediately over the wound, prior to placing the bandage, in addition to a small roll of adhesive tape. Obviously the bandage will be used mainly for the holding of splints in position in the treatment of fractures. Fractures may be divided into three classes:—1. *Simple*: Wherein the bone is broken with but slight injury to the surrounding parts. 2. *Compound*: The bone is broken and the skin is broken or torn and in this manner, germs are able to obtain entrance to the seat of the fracture. In some instances, the fractured ends may protrude through the skin or the wound may lead down to the fracture. 3. *Complicated*: The bone is broken and there may be injury to some important blood vessel, body organs, or nerves. The general signs and symptoms of a fracture of the bone are pain near the break, loss of power in the limb, swelling about the seat of the fracture, and deformity whereby the limb assumes unnatural positions, whilst in many instances, where the bone is close to the skin (e.g., the shin bone), it may be seen or felt. In all cases of fractures, the object of first aid treatment is to guard against further injury and prevent simple fractures becoming more serious, and on no account should a patient be moved until the injured limb has been rendered as immovable as possible by splinting or other methods. Bandages must be applied firmly, but not so tightly as to restrict circulation of blood in the limb, whilst in all cases of fractures, remember to keep the patient warm, for in this manner the effects of shock are considerably reduced. As a general guide, the broad bandage should always be used in injuries to the trunk of the body, for the arm or forearm the narrow bandage, whilst in the case of the thigh or leg, the medium or narrow bandage should be used. Signs of *dislocation* are not unlike those of fracture, as with dislocations there is severe pain of a sickening character at or near the joint, the limb loses its power, the parts of the limb near the dislocation have a feeling of numbness, it is misshapen at the joint, whilst commonly there is also a fixity of the joint. The treatment of a dislocation is broadly thus:—Rest the limb in the most comfortable position, apply cold dressings to the joint, and if these do not give comfort, apply hot fomentations pending the arrival of the doctor, who alone should reduce a dislocation. *Shock*: In almost every accident, shock of a more or less severe nature is found, whilst fright, anticipation of injury, sudden bad news, or the removal of fear and anxiety after prolonged suspense in many instances produce shock or fainting. The general symptoms of shock are extreme paleness, a feeling of cold, clammy skin, and feeble pulse, whilst in collapse the temperature very often falls below normal, and the object of first aid is to prevent it from falling to that point where life is impossible. Treatment of shock is as follows:—Allow the patient to lie upon his back, with the head low, whilst the lower limbs should be raised; plenty of fresh air should be allowed to circulate, and if the temperature has fallen, cover the patient well with wrappings, together with hot water bottles, &c., at the feet. If the patient is able to swallow, hot drinks, such as milk and tea should be given, with sugar added; sugar always materially assists in raising the temperature of the body. In the case of fainting, the best method is as follows:—When the patient is in the lying position, bring the head and trunk forward until the head is almost between the knees, and thus allow the blood to once more regain circulation to the head. *Haemorrhage*: Perhaps of more interest in first aid work on accidents as may befall the man on the land is that of the application of ligatures. The organs of blood circulation are the heart, arteries, veins, and capillaries. The arteries convey the blood from the heart, veins carry it to the heart, whilst the capillaries connect the arteries and veins. Arteries may be found on either side of the windpipe running to the head, again leading under each collarbone down the arm corresponding with the seam of the coat sleeve on inside, whilst again one may be found leading down the back of abdomen, dividing in pelvis and leading through the groins to either leg. In an arterial haemorrhage blood will be found to be scarlet, and should the

artery be near the skin, the blood will be found to spurt in jets corresponding to the beats of the heart. In the case of a severed artery, it will always flow from the side nearest the heart, whereas the blood from a vein will always issue from the side furthest from the heart. Arterial haemorrhage is, when practicable, to be arrested by pressure, position of the body, and elevation of the bleeding part. Pressure may be applied upon an artery in three ways:—1. Digital: This is by the thumb close to the wound. 2. Tourniquet: Pad and bandage. 3. Flexion. The best method of staying the flow of blood is by means of the tourniquet, which is made by tying any small object in a handkerchief or bandage, placing the hardened part very carefully over the artery, and when tying the ends of the bandage on the other side of the limb, tie in a piece of stick about 6in. long. Pressure may now be obtained by means of this stick, and when sufficient pressure has been gained to stay the flow of blood, carefully lock the stick in position. Great care must be exercised in placing the pad over the seat of the artery, and once every half hour pressure should be slackened for a minute or so to allow blood to pass through the limb. In the case of haemorrhage of the vein, the blood will be found to be dark red, flowing in a slow, continuous stream, whilst it will be found to issue from the side furthest from the heart. Elevation of the wound, coupled with pressure by the thumb, will in all cases stop the flow in such a wound as this. Regarding the capillaries, the blood will be very light red, whilst it merely oozes, as after minor cuts, &c., and very slight pressure only is needed to arrest this. *The Ear*: Probably of more interest and a more common accident is that of foreign objects in the eye and insects, &c., in the ear. The ear can be terribly painful, and yet if a little warm olive oil be poured in, any insect will usually float out. Should a grass seed or oat lodge in the ear, and yet perhaps cannot be seen, a much better view of the interior of the ear channel may be gained if the lobe of the ear is pulled upwards and backwards, when usually the object may be located and removed with a very fine pair of tweezers. *The Eye*: When foreign bodies lodge in the lower lid of the eye, they always cause great pain to the patient. In all cases the patient should refrain from rubbing the eye, and if the lid is pulled downwards the object will be seen quite plainly, and in most cases the twisted corner of a handkerchief will brush out the object. Regarding those that may lodge beneath the upper lid, it will be found that these can also be easily removed if the following treatment is observed:—The upper eyelid should be pulled forward, whilst the lower is pushed up, so that the lower lid lashes brush against the inner surface of the upper one and usually dislodges the object at the first attempt. In the case of lime in the eye, a weak solution of vinegar and water will be found very beneficial. *Burns*: A few precautions should always be remembered. If a person catches on fire, for instance a woman's dress:—1. Never run outside into the open air. 2. Lie the burning person flat on the floor, so that the burning portions are uppermost, as flames will always rise, and should the person be standing flames will envelope the whole body. 3. Smother the flames with a blanket, towel, or anything handy. Should the burns be serious, remove any clothing left, except that stuck to the wounded surfaces; do not break blisters, and, if possible, exclude air from the burnt portions by keeping the wound in warm water, or apply lanoline or vaseline. In all cases of burns, after shock will be very serious, and this should be treated as previously mentioned. *Sunstroke*: If a person be not in the best of health there is always the danger of sunstroke when exposed to great heat. The beaming of the sun upon the back of the neck and head of a person will sometimes bring on a sunstroke, the symptoms being sickness, faintness, giddiness, and difficulty in breathing. The patient complains of thirst, the skin becomes dry and burning, the face becomes flushed, the pulse quickens, and the temperature rises to the abnormal until collapse ensues. For treating this the following hints will be found very beneficial:—Remove the patient to a cool, shady spot, upper clothing should be removed, the head and trunk kept well raised, and whilst one person fans the patient vigorously, another should apply cold water to the head, neck, and spine until the symptoms subside. Upon regaining consciousness, the sufferer should be allowed water to drink. *Snakebite*: In treating snakebite, the patient should bear in mind that it is absolutely necessary to keep the venom from the heart, where it will be spread through the whole body. To attain this, immediately place a ligature, if it be possible, between the wound and the heart. Keep the wound low, and encourage bleeding by cutting deeply between the fang marks. Suck the wound, thereby withdrawing the venom, and once assured all poison has been removed, sterilise the wound with Condy's crystals, &c., and remove binding."

HARVEST REPORTS.—During October members of the Branch visited Roseworthy College. An excellent report of the visit was presented by Mr. W. J. Marshman at the meeting held on January 27th. The Secretary, Mr. A. Bowyer, gave the following harvest report:—The Owen district gave varied yields, according to the sowings, early sown giving good returns, whilst late sowings were light. He attributed the marvellous manner in which the crops hung out during the late weeks of May and right through June to the heavy thunderstorm of approximately 2in. of rain the previous December. The paper revealed the fact that the Owen rainfall for the year was 1,445 points, whilst

in the growing period there were 11 in., but 3 in. of this was gauged during the last few days of October. Whilst rust was prevalent throughout the district, members in common gave reports of good samples, whilst early sowings of such wheats as Nawob, Ford, Nabawa, Gluyas, and Crostan gave yields of 27 bush. per acre, but the same wheats sown in late June and early July gave yields nearer 18 bush. In the report the writer made mention of high yields of English barley, and the report showed an exceptional year in oat crops on stubble ground of the following varieties:—Palestine, New Zealand Cape, Early Burt, and Pride of York. Mr. McPharlin also reported Nawob as being subject to disease, but yielding well, with Nabawa and Ford equally as good. Sultan and Crostan, although they showed great promise in early spring, were both affected by rust. The latter variety showed great promise as a hay wheat. In the discussion regarding oats, Mr. H. Bowyer mentioned that a great difference had been shown this season between Algerian and New Zealand Cape. The former, he asserted, were a fortnight later than New Zealand Cape, whilst they did not stand so upright as the latter. He preferred New Zealand Cape as a hay variety, because, whilst growing equal bulk, the stock relished it far more. Speaking on the sowing of oats, he favored early shallow sowing and a hard seedbed for good results. (Secretary, Mr. A. Bowyer.)

SADDLEWORTH (Average annual rainfall, 19.60 in.).

November 7th.—Present: 20 members.

Mr. F. W. Coleman gave a lecture on his visit to Western Australia.

DAIRYING.—The following paper was read by Mr. L. Giles, of the Wirrilla Branch, at a meeting held on March 6th:—"Dairying at present is a very pleasing subject to talk about, for it is the one thing left us to do that shows a reasonable profit. Until recently we have had good prices for wheat, wool, and fat lambs, and that has had the effect of inducing farmers to get rid of their cows and keep to the easier methods of making money. Now that prices for everything else have slumped, farmers are again wanting to run more cows and so get some ready money to help them over these bad times. Dairying has an advantage over other methods of gaining a livelihood on the land, in that the returns come in fortnightly. Therefore, it does not need so much capital to start on as other methods. Farmers shy clear of the cows because of the tie they are, but dairying properly carried out is perhaps the most interesting of callings. We keep records of all cows by weighing all milk and booking all weights. I will divide dairying into three parts, namely, feeding, breeding, and weeding. No person can hope to make a success of dairying if they do not supply their cows with a reasonable amount of the right sorts of feed. Always keep in mind a balanced ration, and always study economy; do not feed one sort of fodder to the cows if some other fodder equally as good at a lower figure can be obtained. A balanced ration is a certain amount of roughage or carbohydrates, concentrates, or proteins with some green fodder included, or failing that, some root crop such as mangolds or turnips. Carbohydrates can always be grown on local farms by cutting ordinary cereal hay and either feeding it as hay or chaffing it. Do not use mouldy hay, it is likely to give the cows indigestion, a complaint that good cows are very subject to if one tries to get the best out of them. It also may spoil the cream, and second-grade cream is not profitable. It is quite possible to give too much chaff, but it is not possible to get a cow to eat too much good, clean hay. There are several kinds of concentrates that can be fed, but usually crushed oats and bran in about equal quantities make the best and most economical mixture. Feed at least two kinds of concentrates—more if they can be secured without adding to the cost of feeding. Linseed meal is a splendid concentrate to feed if other concentrates are not cheap, but at present prices linseed meal is out of the question. If linseed is equal in price to double the quantity of bran or crushed oats, it is a reasonable proposition, but with bran £3 15s. per ton, oats 1s. 3d. per bush., and linseed meal £12 per ton, linseed is too dear. When using linseed, always soak it in water. Feeds of linseed must not be fed more than 2 lbs. or 3 lbs. per day. It is not possible to set a given quantity for each cow, individual cows differ in their requirements, and much depends on how much they are getting in the paddocks, but about 5 lbs. to 10 lbs. of chaff twice a day, with 2 lbs. of concentrates for every gallon of milk the cow gives, will show best results. We feed 3 lbs. of concentrates per gallon to our cows, but I would not advise that much for ordinary dairying. A sheaf of hay per day is a good help, and aids the cows to digest their feed. For a few months in the year, while the grass is at its best, we have proved that hand feeding is of very little help. With us it lasts for about two or three months, that is, of course, when dairying is the most profitable. It can only be done when the grasses are at such a stage that they are a balanced ration in themselves. To over feed a cow means that one is wasting feed and money. To under feed means that the cow has to take a bigger proportion of what she is getting to keep her alive, and so does not have enough left to make milk and butterfat. Good cows pay to feed well, because they turn what they eat into milk, but bad cows put it on their bodies in

fat, and the dairyman loses it. *Pure-bred Stock.*—What would the farmers of South Australia think of a farmer that got his seed from a neighbor that never grew more than 10bush. per acre, while he had other neighbors continually growing 30bush.? If a farmer did that he would be the laughing stock of the district. That is exactly what the dairymen are doing that are breeding from scrub bulls. All have heard the saying, "Like father, like son." Generally that is right so far as purebred stock goes, because for generations there has been the one class of stock, and there is nothing else in the blood to throw back to. That is the reason there are very few "duds" in pure-bred stock. The same does not apply to mongrels, because there is no telling how a mongrel is got, one time it will throw back to one sort of ancestor and another time to another sort. Hence the reason of so many 'duds.' Pick the breed you think most suitable, buy a pure bred bull of that breed and stick to it. It only takes a few generations to make them nearly pure. Do not forget that the bull is half the future herd, so be careful to see that his ancestors have good milk records behind them. There is no excuse to-day for anyone in South Australia using scrub bulls while the Government pays one-half the price for good, pure-bred dairy bulls. There are four breeds of cattle in South Australia recognised as dairy breeds, and I would not advise a dairyman with one of those breeds to change to another breed. The good cows of any of the breeds are better than the bad cows of another breed. Ayrshires are small and very hardy cattle, and are supposed to be able to do well under conditions that would be too hard for any other breed. Their milk contains a higher percentage of casein than any other milk, and is particularly good for making cheese. In South Australia they usually fill the fourth place as butterfat producers and are not very popular. As the casein is not taken out of the milk when separating it makes a good fodder for pigs and calves. The Jersey is the best known breed in this district. Its strong point is its high butterfat percentage in the milk, the highest of any breed of cattle. The breeders of the Jersey generally claim that they are the most economical butterfat producers. They usually fill second place in South Australia as butterfat producers. The Milking Shorthorn is the most easily fattened for beef of the four breeds. That, combined with being good milkers and next to the Jersey in butterfat production makes them a very popular breed. They are the largest milk producers, and their milk is also the most wholesome of any animal that is milked for the use of the human race. Their milk contains more sugar than that of any other cows. They are next to the Ayrshire in casein and are lowest in butterfat, which makes their milk especially good for the production of cheese and to feed after separating. They are the largest cattle of the dairy breeds, so the good beefers and are easily the best vealers of any breed of cattle. Since dairy testing started in South Australia, they have never failed to secure the top place, often by very large margins. *Weeding.*—This needs very much more attention in South Australia. It is only by testing individual cows that we can find out the best cows. The biggest milkers may be quite a long way from the best cows in the herd, so also may the cows with the highest butterfat percentage. It is only by weighing the milk and testing it that the true position of the cows in the herd can be placed. It is not much good just testing cows once, as the cow may secure a lucky test or an unlucky one. The best way to test is to weigh all milk received and to get the factory to test the milk of every cow for each milking for 24 hours about once a month. It is only by testing that a dairyman can know which cows to weed out, and it is very necessary to weed out the worst cows and to replace them with heifers from the best cows. If a dairyman is to be successful, it is important to always have first grade cream. This is a simple matter if the following few hints are observed:—See the cows are well fed on good feed and that they eat nothing to spoil the cream. Keep the separator and all utensils clean. Stir the cream regularly at least twice a day and stir well. Send the cream to the factory at least twice a week. Top-dress pastures for dairy cows; it helps the grass to get away quickly and makes a great deal more feed. The feed is also a much better quality, and keeps the cows healthy. Regular habits are very necessary for the dairyman. Milk as nearly as possible to the same times and be even more particular to feed at the same times; irregular feeding upsets cows more than irregular milking. Get as many cows as can be arranged in, in autumn or early winter, to obtain full advantage of green feed. Cows are then just in when butter is at its highest price. Never upset dairy cows by hitting or kicking them or in any way knocking them about. Get cows that are coming in shortly in good condition; poor cows cannot do themselves justice. See that vessels that the calves drink out of are kept clean and skim all froth off the milk. As soon as the calf is old enough to eat, give it chaff and crushed oats. Skim milk is usually laxative enough, but if more is needed, add bran. A small handful of pollard stirred in the milk is a help, but do not put enough to stop the calf from drinking. If the cows have sore teats, Animol ointment is best. Always keep a drench of some sort on hand. Last, but by no means least, is the question of water. Always try to run cows where they can get plenty of good, clean water to drink. A cow that is milking heavily will drink four or five times a day." (Secretary, Mr. A. Blundell.)

YORKE PENINSULA DISTRICT.**(TO BUTE.)****BOOR'S PLAINS.**

January 8th.—Present : 20 members.

POULTRY.—Mr. F. Day read the following paper :—For the last few years poultry farming has made such rapid strides, and is occupying our minds to such a marked degree, that the industry is frequently referred to as being the only one at the present time that is paying its way. The British markets are now beyond the experimental stage, and offer a good steady demand for our produce. To make poultry farming a success, one must have a certain liking for the birds, and must be observant, especially where there are large flocks kept, and large numbers running together, as any birds which are off color are easily overlooked, and it may be the cause of sickness going through the whole flock. The poultryman's success depends on his knowledge, methods, and the birds he keeps. The actual amount of knowledge that is required is not very great, but it is surprising how easy it is to go wrong, resulting in loss of time and money, such results being put down to the poultryman's bad luck, which, to a very small degree, it might be, but generally it is through lack of knowledge. As a rule the so-called lucky ones leave nothing to chance, therefore when wishing to build up a big plant, my advice is "hasten slowly." One way to make a start is to purchase day-old chicks, and rear them to maturity, thereby gaining valuable experience, or by purchasing a pen of breeders and hatching them under broodies or in an incubator. Another way is by buying eggs, but no matter which way you start, always get the best stock or eggs that you can afford, and always go to a reliable breeder, even if you have to pay more ; but remember you are building up a new industry, and what good will up-to-date sheds, plant, and balanced food rations be, if the stock are not bred for egg production or table purposes. I do not propose to deal with the working of the incubator, as there are so many factors which influence the results, that it would be useless and too lengthy to discuss it at the present moment. *Care of the Chick from the Incubator.*—Care must be taken that the chick is not chilled during removal from the incubator to the brooder, which should have been previously heated to the correct temperature, 95 degrees for the first week, and gradually reducing it week by week, until they are five or six weeks old. Some breeders take them away at two weeks old, and put them into cold brooders, certainly a saving of time and expense, but those methods are more applicable where there is plenty of help. I have used the cold brooder at that age, but prefer the heated brooder for the longer period. The feeding I adopt for the first few weeks is comprised of one part pollard, half bran, 10 per cent. buttermilk, with charcoal broken very fine. After two weeks old I add one heaped teaspoonful of sterilized mineral bone with iodine. This feed is in the form of dry mash, and is always before them. I do not give any wet mash. From a fortnight old, fine grain is sparingly fed at night for the first five or six days, and then gradually increased in quantity and coarseness. If grain is fed lavishly at first, it is liable to bring on diarrhoea. If there should be an outbreak of diarrhoea, increase the quantity of buttermilk powder by 5 to 10 per cent., but the quantity in the formula should

keep it in check. At this age, green feed should be fed, as much as they can eat. Regarding brooders, I prefer the blue flame, with the canopy or hover type. A brooder with a hover 5ft. in diameter will be large enough to accommodate 500 chicks for the whole of the period that they require the brooder. As a rule the brooder for 200 chicks, or any other size, is only large enough for one week. I believe in starting the other end, and having the house large enough for the family when they grow up. If rearing for egg production only, it is advisable to kill off the cockerels the moment they show their sex. They do not pay to rear, and they cost as much as pullets to feed. We will assume that you have reared the stock approaching roosting. This is a trying time, and various methods are used to get them to roost. A good method is to arrange perches about 12in. from the ground, being of 3in. by 1in. hardwood, and placed about 6in. apart. At roosting time the chickens roost for a short time before starting to crowd, but before allowing them to get to that stage I place empty sacks over those that are on the perches, and catch the balance and place them under sacks also. Leave these sacks on until it is dark, and they are then taken off, and the chickens stay on the perch without any trouble. I do this for about a week, and then place perches higher and wider apart, and then have practically no further trouble, except to keep an eye on them to see they do not crowd or roost on each other. By this time all the cockerels should have been separated from the pullets. Still continue with the dry mash and plenty of green feed. I use the following ration:—Bran, half part by measure; lucerne meal, 5 per cent.; pollard, two parts; meat meal, 5 per cent. of the weight of the above; charcoal, 5 per cent. by weight; salt, 20 per cent. by weight. If for fattening purposes, a mixture of bran and pollard, barley meal, maize meal, mixed with skim or separated milk, and 5 per cent. brown sugar, and their liberty curtailed, is recommended. I favor the intensive system; it certainly means extra expense for suitable yards, but the expense more than pays for itself before very long. Some prefer the semi-intensive, but objection to that is the confinement of the birds at various periods, and at such times the birds will frequently fret on account of the confinement, and go off laying. The aim of the poultry farmer, or anyone who keeps fowls, is to keep the best they can possibly afford, and, of course, breed from hens of high egg production. Selection of laying and breeding stock is an art, and is only acquired by experience, and should be learnt as soon as possible. This is the secret of successful poultry farming. A farmer may have 1,000 fowls, which are unprofitable, but if the fowls are severely culled, it is more than likely that his loss will be turned into a profit. Learn to pick the workers. Houses for the intensive system should be about 8ft. high in front and 6ft. high at the back, with a cement floor for preference. In some cases the front is enclosed for about 3ft. high, and others to within 1ft. of the top. I prefer having only from 1ft. to 2ft. of the bottom filled in, to get the full benefit of the sun. The floor should be covered with old straw, and do not at any time use any material that is, or has been, at any time mouldy or musty. I have been using red sand, and find it very good, but on a farm, straw and other such like materials are easily obtainable. If wet mash is fed, feed early and regularly; early feeding is conducive to increased laying. Be sure to keep the troughs clean, and do not give more than they can clean up in about 20 minutes, and if there should be any left over, go around and clean it all up, and do not leave it lying about to go sour. Be sure there is an ample supply of good, clean, fresh water, and in the hot weather see that it is kept in a cool spot. In general outline, the heavy producer is wedge shaped, with the body widening out to the rear, which has breadth and depth, and has a broad back and well-developed chest, the broader and flatter the back the better, and she presents the appearance of being neat and trim, and the whole time she is active and searching for food, usually at the end of the laying period the heavy layer looks very shabby and unkempt. A fairly long, straight breast bone; a breast bone curving up at the rear is not good. The legs should be fairly long and wide apart, and should have long, fine, and supple pelvis bones. The greatest care should be exercised in choosing the male bird, for his blood will run through the whole flock; but if there is only one hen not up to standard, only her chicks are likely to be affected. This point must not be overlooked, and shows how important it is to choose only first-class males. If possible, the male should come from single-tested stock, whose mother, during her pullet year, should have laid a minimum of 220 eggs, weighing 20zs. Never use a bird that is not masculine in appearance and virile, and the bird that has fight in him, and objects to anyone touching the hens, is much desired. Discard all birds for breeding purposes with wry tails or twisted breast bones, narrow backs, and flat chests. The eyes of the male should be bold and outstanding, with long and somewhat narrow head. Do not use a bird with an over-heavy comb, and the comb and gills should be fine and smooth to the touch; an over-heavy comb indicates coarseness. The breast bone should be as long and as straight as possible, and discard one with a hook up at the back. Do not breed from undersized males. A very annoying feature is lack of fertility, and if proper conditions exist, fertility is then a matter of attention to details. An over-fat male or female will cause poor results. Infertility in females is usually caused by over fatness, often caused from under exercise, and too great a portion of starchy foods in relation to the protein matter. There is a great diversity of opinion regarding the results of feeding wet or dry mash. The one big feature in feeding dry mash is the saving of time; consequently, one man can look after a greater number of birds, and, by having large hoppers holding many days' supply. My hopper holds three bags and lasts three weeks for 150 birds. The wet mash advocates claim they get more eggs from their method; but as fewer birds can be attended than is the case with the dry mash, I consider the advantage is with the dry mash feeding. (Secretary, Mr. S. Chynoweth.)

PASKEVILLE (Average annual rainfall, 15.64in.).

March 3rd.—Present: 17 members.

LIVESTOCK FOOD VALUES.—Mr. L. Moat read the following paper:—"All animal food-stuffs contain certain digestible nutrients, each serving a definite purpose. By far the most important of these are albuminoids. Albuminoids are composed of carbon, hydrogen, oxygen, and nitrogen; they closely resemble the albumen or white of an egg. Bone and muscle, as well as milk, consist largely of this substance. If an animal's body is thoroughly dried, albuminoids will constitute about one-third of the weight. Growth as well as wear and tear can only be supplied by albuminoids. The next most important of the constituents are carbohydrates. These consist chiefly of sugar and starch. They contain carbon hydrogen and oxygen, but not nitrogen. The carbohydrates in the process of digestion are oxidised in the tissues, and the heat is given off. Thus they supply energy and maintain bodily heat. The other constituents are of less importance. Fats are practicably interchangeable with carbohydrates, 1lb. of fats producing $2\frac{1}{2}$ times as much heat and energy as sugar or starch. The mineral substances need occupy little attention, as they are usually present in sufficient quantities. Many careful experiments have been carried out with the object of discovering the exact ratio of albuminoids to carbohydrates and fats that are required by various animals. Naturally, the young growing animal requires a greater proportion of albuminoids than the aged beast. The youngster is building up muscle and bone, and nitrogenous materials are essential. The calf of six months, therefore, will require a ration with an albuminoid ratio of 1 to 5, whereas a two-year-old beast will do on 1 to 8. The young pig requires a ration rich in albuminoids in the proportion of 1 to 4.

Pasture.—A knowledge of the approximate value of the more commonly used fodders is important. The feeding value of pasture grass varies greatly. Good pasture is an excellently balanced ration, the proportion of albuminoids to carbohydrates being about 1 to 6. While the plant is vigorous and healthy, the ratio is higher. As the year advances, however, the nutriment becomes concentrated in the seed. After the seed falls, the value of the pasture rapidly declines. The nature of the grasses of the same species varies greatly in different localities. Stock will fatten in one locality and lose condition in another upon grass apparently about equal. An experienced man can best judge the value of a pasture by the condition of the stock. Much can be done by manuring the pasture to increase the richness; no concentrated food is required to balance a good pasture ration.

Straw.—The feeding value of straw by itself is very slight. This is particularly so in the case of wheat straw. The available albuminoids in wheat straw are as low as 4 per cent., as against 36 per cent. carbohydrates. It is estimated that a horse will consume as much energy in chewing and digesting wheat straw as he will derive from the fodder. Barley straw is higher with 8 per cent. albuminoids and oat straw, is considerably more nutritious; it contains 1.2 albuminoids, as against 38.6 per cent. carbohydrates.

Hay.—Hay varies in its feeding value, perhaps more than any other fodder. Australian hay made from wheat and oat crops is slightly less nutritious than the best meadow hay of England. But the cost of gathering is so much less, that it constitutes a wonderfully cheap and valuable fodder. As the crop advances, the albuminoids are concentrated in the seed, and while the proportion may not show a decline, the actual feeding value is lessened by the straw becoming less easily digested as the plant matures. If the crop be harvested before the grain sets, the feeding value will be better distributed throughout the straw, and though the loss of weight will be slightly greater, the actual feeding value will be higher. The richness of hay varies with its length, the shorter being the richer. Nevertheless, it is doubtful if it is wise to harvest the shorter crop for hay. It will generally be found wiser to cut the higher crop and add slightly more corn. Varieties such as Huguenot are of high feeding value. Oaten hay should show 4.5 per cent. albuminoids to 45 per cent. of carbohydrates and fats, while wheaten hay shows 3.75 per cent. to 48 per cent., i.e., roughly a ratio for oaten hay of 1:10 and for wheaten hay 1:13. Lucerne hay is rich in albuminoids, the analysis showing 12.3 per cent. to 40, or almost 1:3; silage shows 2.2 per cent. to 20.

Roots.—These crops contain a very high proportion of water, and the relative proportion of nutritive matter is, therefore, low in proportion to weight. Turnips contain about one of albuminoids to seven of carbohydrates; swedes are slightly richer. Mangels are about the same, but improve when stacked. The feeding value of potatoes is about double that of turnips.

Balanced Ration.—It will be seen, then, that good growing pastures of green fodders are, in themselves, a balanced ration. Except when a cow is milking very heavily, or in the case of a very young animal, if a plentiful supply of good grass or green food is obtainable, nothing more is required. Lucerne is particularly high in albuminoids, and a better value from the food will be obtained if it is mixed with a ration of hay or poorer pasture. Sorghums and maize, on the other hand, are relatively poor in albuminoids, and to obtain best results a small allowance of concentrated food should be given. Seeing that it is almost always the albuminoids in a ration that require building up, it is well to remember that a working horse and a fattening beast of two years each require about $2\frac{1}{2}$ lbs. of this constituent per day. A sheep to fatten will require approximately 1lb., a five months old pig will

require 1½lb. Obviously an unbalanced ration means waste. Albuminoids are usually relatively expensive, therefore it is extravagance to supply more than the requirement. On the other hand, if 12lbs. of carbohydrates are required for a two years beast, and 20lbs. are supplied, the beast will gain practically nothing if the albuminoid ratio is deficient. Oats, bran, and pollard are well-balanced rations, and may be added when both carbohydrates and albuminoids are required. Barley and maize are strong in carbohydrates and relatively weak in albuminoids. Molasses practically contain no albuminoids, but about 70 per cent. carbohydrates. Podding plants are rich in albuminoids; beans carry 25 per cent. and peas 20 per cent. Both lucerne and hay lucerne (growing) are also rich in this respect. If a general shortage has to be made up, it can best be done with oats, pollard, and bran. Use concentrated foods only for the purposes of adjusting the balance. They are most useful for this purpose, but it is easy to handle them extravagantly." (Secretary, Mr. J. Prouse.)

WESTERN DISTRICT.

COLLIE.

November 5th.—Present: Eight Members.

MACHINE *versus* BLADE SHEARING.—A paper on this subject was read by Mr. E. Olsen. "Blade shearing is the cheaper method. Having 900 sheep shorn by contract with machines and shearers would cost £22 10s. for shearing, £5 10s. for shed hands, and 10s. for fuel and oil—a total of £28 10s. After taking out 30s. for shearers' food, the cost is £27. If any stand is faulty, one has to pay the shearer at the rate equal to the sheep he would have shorn during his enforced idleness. In the case of

a broken stand, one is faced with the double cost of the repairs plus the shearer's wages. In the case of shearing 900 sheep with three blade shearers averaging 75 sheep a day, costs would be £18 for shearing and £2 10s. for shearers' food, equals £20 10s. Two men can look after the requirements of three blade shearers in the shed, but five men would be needed to look after three machine shearers, and thus another burden would be laid on the housewife. Machines injure the sheep much more than the blades. When the feed is scarce sheep do not pick up condition easily if they have been roughly treated. The machined fleece is usually torn up the back, and rough and ready handling makes it difficult to pick and throw in order to skirt it properly." (Secretary, Mr. D. Gunn, Mount Cooper.)

GOODE (Average annual rainfall, 10.20in.).

Meeting held November 5th. Present: 19 members and five visitors. Captain A. Browne read a paper, "Insurance Against Drought," and the Secretary announced the results of the local Crop Competition, Mr. J. Paech being the winner, with Mr. J. Cooper second. (Secretary, Mr. E. Fear.)

KAPINNIE.

July 25th.—Present 15 members.

FALLOWING.—The following paper was presented by Mr. B. Rogers:—"Choose a paddock which has carried a rotation of crops or a field which has not been cultivated for a few years, but used for grazing purposes, because if land is cropped successively for a number of years, it becomes wheat sick. Fallowing should begin immediately after seeding and be finished before grass and weeds have gone to seed. After the first ploughing, the land can be left for a week or so and then harrowed to kill any weeds which the plough has missed. If more weeds show, or a crust is formed on the surface, a rigid tine is better; it tends to shake the soil from the roots. It also proves satisfactory in red clay; it shakes the finer soil to the bottom and brings the clods to the top, thereby preventing the surface from running together in wet weather. If fallow is worked throughout the period when weeds are showing, it may be left alone until summer and then worked lightly after rain. It can then be left until seeding. In a district with a comparatively light rainfall more emphasis should be laid on the destruction of weeds and the aeration of the soil rather than on the conservation of moisture."

SHEARING.—Mr. C. Lukraft read the following paper at the meeting held on August 22nd, which was attended by 11 members. Shearing should be done as soon as the green feed gets a good start and the weather begins to warm up; then the sheep get the full benefit of the feed and they will be in good condition to carry them through the drier months. Grating is an important item in the shed equipment, especially for yarding sheep overnight. Another grating should be laid down for 50 to 100 sheep per shearer. A turning-out pen should be made for the shorn sheep; this will save the shearer a lot of work and time when the pen cuts out half way through a run. The shearing board should be at least 7ft. wide and situated where there is plenty of light and little draught. A serviceable wool table should be procured, so that pieces and second cuts that are gathered with the fleece can fall through. Box presses will prevent the wool from getting mixed and help the shed hand to keep up the work. Bales should be branded with stencil plates. It does not pay the small sheepowner to make too many classes. The main object is to keep the stained pieces from the clean fleece wool. It is better to have clean wool with stained pieces than stained pieces in the clean wool. The bellies should be separated and any broken or faulty fleeces classed out. If there is not enough to make a bale full they should be torn up and put with the pieces. A good watch should be kept for lice while shearing. If the sheep rub very much or the wool tends to fall out and is of a dry, discolored, and lifeless appearance, the sheep should be dipped soon after shearing." During the discussion which followed, Mr. Wagner said three or four box presses were unnecessary unless the shed was large enough to warrant them. The writer, in reply to questions, preferred blades to machines if the shearers were not competent, and also that sheep should be dipped six weeks after shearing unless lice were very bad. (Secretary, Mr. E. Wannon, Brimpton Lake.)

KELLY (Average annual rainfall, 11.92in.).

August 16th.—Present: 21 members and six visitors.

MARKETING FARM PRODUCTS.—The meeting was held at the residence of Mr. J. Beinke. In the course of an address on the above subject, Mr. Freeth said that, in the future, they would have to depend to a large extent on by-products, because of the lowered price of wheat and wool. To secure the maximum returns, it would be necessary to improve the quality of produce and have an organised marketing system. At

present they were practically dependent on stores to take their eggs and butter. Eggs, said Mr. Freeth, could be improved in quality. Only a very small per cent. of country eggs were of first quality, and he was of the opinion that consumers would be quite prepared to pay considerably more for a guaranteed article, which was borne out by the high prices obtained for Red Comb eggs. Mr. Freeth suggested that an organised system of collecting and sale would be a great advantage in the disposal of such lines as butter, eggs, sheep and other skins, tallow, &c. Supper was provided by the ladies. (Secretary, Mr. M. Martin, Kimba.)

February 2nd.—Present: 12 members and six visitors.

PASTURE IMPROVEMENT.—Mr. Martin read the following paper:—"In introducing this subject, I have in mind the low price of cereals, which have hitherto been our main source of income. Under present prices, it seems that if we carry on with it, it will be our biggest expense. In selecting other means of livelihood, stock raising suggests itself. In order to make this a success, it is necessary to have an adequate supply of fodder, either in the form of a cereal hay or grass. I shall deal mainly with grass fodder. As a district ours is not an ideal pasture country, as we have no good pasture grasses; the chief native grasses are barley, spear, and a perennial bunch grass common to our natural plains. Barley grass, although a fairly hardy and vigorous grower, is not good pasture. Stock do reasonably well on it, till it starts to make ear; it then becomes unpalatable, and stock lose condition rapidly if forced to eat it. The seeds when ripe are a danger to sheep, getting in their eyes, causing blindness, unless they are given almost daily attention till the seeds have all been shed. They also collect in the mouths of horses, causing trouble. This plant also acts as a host plant for take-all, and is particularly undesirable in a wheat district such as this. Spear grass does not occur to any great extent, except following a burn, so can hardly be classed as a dependable pasture. The perennial grass of the plains is also of little account, although it will yield a fair growth of feed under favorable conditions and grow rapidly after an early rain. There are not many grasses or pasture plants that lend themselves to our local conditions. Those I have in mind as most suitable are lucerne, Wimmera rye King Island melilot, and evening primrose. Lucerne is considered the world's best fodder, both in yield and food value. Although it yields best under irrigation, recent

THE ADELAIDE CHEMICAL & FERTILIZER CO. LTD.

experiments have proved it to be a drought resister as well. It will grow rapidly when the first autumn rains fall, when all other feeds are dormant. It will also provide green feed throughout summer, making particularly good growth if any summer rains fall. We have a two-acre plot sown in 1927, and it has lived through the drought for six months and had a continuous stream of drift sand going over it. The best time to seed is autumn, sowing 4lbs. to 5lbs. of seed mixed with 100lbs. of super to the acre. When it has been established 12 months it should be cultivated with a spring-tooth cultivator with worn out and very narrow shares. A combine is best suited for this, and some super can be drilled in at the same time. When once established, lucerne will last many years, and if not too thick, wheat can be planted in the same field. Being a nitrogenous plant it will be of distinct advantage to the growth of wheat. Care should be used when grazing stock on lucerne, not to turn animals on it empty, or they are likely to blow on it, also continuous feeding of it is fatal to the plant. Wimmera rye grass is a splendid fodder, hardy, and will grow under any conditions that barley grass will, and there is no period of growth that stock will not eat or do well on it. The best way to establish it is to mix it with seed wheat at the rate of 6lbs. to the acre. This amount will not greatly affect the wheat yield, and will make a good seeding for leaving out the following year. King Island melilot is a vigorous growing, upright legume resembling lucerne, but it is an annual, and although liking favorable conditions, will do very well on sandy soils. Its seed will lie in the ground for years, thus guarding against seasons that are not favorable for good growth and seeding. Evening primrose will withstand droughty conditions, and will yield a lot of summer green feed when most other food is dry. Though not a plant of high food value, it is very good for stock when mixed with dry foods. This plant is used extensively in the lake districts, to check drifting sandhills; it seems to do best in soils of that nature." (Secretary, Mr. H. Martin, Kimba.)

#### KYANCUTTA.

September 2nd.—Present: 19 members.

**SELECTION OF SEED WHEAT.**—The following paper was contributed by Mr. F. Daniels:—In selecting seed for the next crop, thought must first be given to the class of land that it is intended to crop. Land can be divided into three classes, new ground, stubble or grass land, and fallow. For new ground, select wheats that will grow fairly high, so that it will be above the small sticks that are often found in the first crop on scrub land. These wheats should be of a flaggy nature to give a good burn from the stubble. Late Gluyas and J4 are the two best wheats for new ground. These, if sown about the first or second week in April with 50lbs. of graded and dry pickled seed and the same quantity of high grade super per acre in a normal year, will give a good return. For stubble on grass land, select wheats that will grow quickly, so that they can get away from grass and weeds. The two best wheats for this land are Golden Drop and Canberra. The same rate of seeding as for new land is recommended for stubble and grass land. The two varieties I would select for fallow are Late Gluyas and Nabawa. These two wheats, under favorable conditions, will yield a splendid harvest. They do not grow so rank as some of the other wheats, and they are not so likely to go down if rough weather is experienced. If the ground has been worked well, sow 60lbs. of graded and dry pickled seed with 90lbs. of high grade super per acre, but if the ground has not had proper cultivation, do not sow more than 50lbs. of seed with 90lbs. of super. All seed should be graded; 50lbs. of graded is equal to 60lbs. that have not been graded, and one will always have clean seed, free from barley and other foreign matter. Dry pickling is recommended because it saves a lot of labor during the busy time. Grading and pickling can be done in the one job; one man can put through about 50 bags per day, and this can be done any time before seeding. After four years' trial I am convinced that dry pickle is from 15 per cent. to 20 per cent. better than any of the wet pickles.

**SHEEP ON THE FARM.**—Mr. C. Kammerman read the following paper:—"With wheat at its present low price, it is essential for every farm to have some sideline. Sheep are the most profitable sideline, in fact, no farm is complete without them. For the average farm, ewes and lamb raising pay the best, even though they take up more time and attention than dry sheep. Regarding lamb raising, there are three courses open to the prospective breeder, namely:—(1) To yard the ewes for two nights a week for a fortnight, admitting rams; (2) to mate ewes the usual way by admitting rams at mating time about January; (3) to let the rams run with the ewes all the year round. The latter course for the beginner has its merits. The writer prefers the first course. The sheepbreeder, having all his ewes lambing within a few days of each other, can give them much better attention than if ewes are lambing over a number of weeks, get a much higher percentage of lambs, and there is less mortality among the ewes. In conclusion the writer's advice is get sheep on the farm, but do not overstock." (Secretary, Mr. D. Fitzgerald.)

## LAURA BAY.

November 11th.—Present: 14 members.

FARM POULTRY.—Mr. C. Collins read the following paper:—"Every farmer keeps fowls, and generally has trouble with them during the long dry summer. With a little care, much loss can be saved. Clean, fresh water should be given. The greater the variety of food the better. Give green feed regularly if possible; not a lot at one time; this may do harm if the fowls have been on dry food for a month or two. Screenings or crushed grain fed in flat tins help the chickens. Give a fair amount of wet pollard. Feed as much as possible on firm ground. Soft damp ground is good for a scratching place. Break up fresh bones and give shell grit. Roup is the worst disease and the best remedy is cleanliness. Do not allow half-grown chickens to roost on the ground. Get them up on the roost, which, although it should not be closed in, ought to be well sheltered. Good shelter and shade are needed during the daytime. Breed from matured stock and get a good rooster when possible. Black Orpingtons are good setters. White Leghorns and Minorcas are the best layers. Have a few coops, so that the setting hen can be kept to itself. Select large eggs for setting. For marketing, gather the eggs as often as possible and keep in a cool place. Have a pen to keep young roosters in. Old hens should be culled out, and any with crinkled combs or rough scaly legs or spurs should be sold or killed. For tick and lice, old car oil and kerosene mixed is recommended to be sprayed on the roost. Olive oil smeared on the body is useful. When eggs are cheap, preserve them, also boil some hard and feed to young chickens. I do not recommend incubators for farm use. To keep other kinds of poultry needs much attention. Turkeys do best with a large run and allowed to set anywhere, but are likely to meet trouble with foxes. Ducks are fast growing and profitable." (Secretary, Mr. W. Edson, Ceduna.)

## PINBONG.

December 6th.—Present: nine members.

FENCING.—Reading a paper on this subject, Mr. C. Scholz said very often fences on the farm were badly neglected. For posts, he suggested titree, and if these were not available, either kong mallee, black oak, or pine. If blackoak posts were used, they should be barked before being put into the ground. He favored a fence 3ft. 10in. high, with posts 16 yards apart, and one iron post between, and one wooden dropper between the iron post and the wooden post. With two barbs and four plain wires of 12½ high tensile wire, one would have a strong fence that would keep all stock within bounds. A meeting was also held on November 8th, there being present 10 members. The subject, "Boys for Farm Work," was discussed. (Secretary, Mr. C. Scholz, Yaninee.)

## YADNARIE (Average annual rainfall, 14.09in.).

March 3rd.—Present: Six members.

PREPARATIONS FOR DRY SEASONS.—Mr. E. Spriggs read the following paper:—"The majority of farmers in this district only receive a good hay cut once in about every four years, hence ample provision should be made for reserve fodder supplies. Sufficient hay should be cut to tide over at least a period of two years. A most important point in the conservation of the hay is the erecting of weatherproof stacks. The centre of the stack should be kept well above the walls, so that an allowance is made for the sheaves settling down. Each sheaf should be so placed with the round side downwards, care being taken to see that it overlaps the twine of the sheaf upon which it is laid. There is no doubt that the harvester and reaper thresher are great labor-saving machines, but it is a good plan to reap portion of the crop with a stripper, so that a supply of cocky chaff can be conserved. If a good stubble paddock is available, bind some of the straw for covering the chaff. Care should be taken not to overstock, and every farmer should dispose of all surplus horses, cattle, and sheep. (Secretary, Mr. E. Spriggs.)

## YEELANNA (Average annual rainfall, 16.03in.).

November, 1930, meeting.

POULTRY ON THE FARM.—Mr. J. Payne read the following paper:—"All farming is essentially mixed farming, and mixed farming in Australia, for the most part, consists of wheat, with sheep and wool in second part. The last two years, however, have been years of declining wheat and wool prices, and this, coupled with high costs of production, has been a severe blow to those who depend solely on our staple products for their income. The progressive farmer is now arduously searching for some means by which to augment his rapidly declining income. *Choice of Birds.*—A branch of the farm which does not receive the attention which it deserves is the poultry run. The first procedure is to choose birds which are to form the nucleus about which the ultimate flock

is to grow. The following questions should be considered:—1. What do I require: egg-producers or a general utility fowl? 2. How many breeds can I keep? 3. What capital can I spend on the project? I consider two breeds quite sufficient. If two breeds are chosen, I recommend Black Orpingtons and either White Leghorns or Rhode Island Reds. If, however, one breed only is chosen, I favor Black Orpingtons. This breed is one which combines flesh with egg production, is hardy, and an ideal farm bird. Having decided on the breed, try and get someone with a knowledge of poultry to choose them for you. A number, say six, good second-year hens and a 12-months cockerel should give a satisfactory start. These seven birds would cost from five to seven guineas. Do not buy inferior birds. Although a farmer will often pay big prices for stud sheep or choice seed wheat, he begrudges two or three guineas for a good cockerel. *Housing.*—The initial purchase would comprise a breeding pen, and if a breeding pen is erected it should be sufficient for the first year. The house should face north-east. It should be 6ft. high in front, sloping to 5ft. high behind. The back and two sides should be fully enclosed and a windbreak of 2ft. 6in. erected in front, the remaining 3ft. 6in. in front to be enclosed with wire netting. A house 10ft. x 6ft. should be ample. The birds should be shut in this each night and not let out next day if it is at all damp. Two flock yards will be necessary: one for mature hens, one for pullets. This house should be built on the same lines as the breeding pen, and should allow for three square feet of space for each bird. The houses may be built side by side, then the run can be arranged that the birds use it on consecutive days, or it may be divided. On no occasion should the male birds be allowed to run with the laying flock. With such societies as the Red Comb Association in being, it is possible to secure an extra 2d. a dozen for guaranteed infertile eggs. This is wonderful pay for a little care. Ventilation of houses calls for special attention. The vents should be so arranged that the air current strikes the roof first and is then deflected on to the fowls. I was recommended to put in front of a house a glass shutter; this was raised at night and during cold wet days. It obviated draught, whilst still allowing light to enter. The fowls were found to commence their lay more quickly and sustain it for a longer period. This idea is hardly practicable in big houses, but is ideal for the breeding pen. Blinds, however, prove very efficient for night usage. *Feeding.*—Nothing but the best and purest of foods should be used. Food is given to birds for three main reasons:—1, To build up the waste properties of the body; 2, to promote body warmth; and 3, to produce eggs. The first two are, to the bird, of primary importance. If, therefore, the fowl is deficient, the egg production suffers. Thus very often when hens cease laying, it is because they do not receive sufficient food to fulfil the three missions of that food. The greatest food economiser is a good house. Fowls must be fed regularly. If their food comes late and they have been excitedly jumping at the netting for half an hour, a great deal of damage has been done to their systems. Then follows the usual adverse consequences on egg production. An approved sequence for poultry feeding for egg production is as follows:—Wet mash in the morning, green feed at midday, grain at night. A recognised formula is as follows:—Bran, 1 part; pollard, 2 parts; green feed chopped, 30 per cent.-80 per cent. of above according to season; 5 per cent. of above, meat meal. The amount per bird is about 3ozs. of dry constituent of mash. Green feed at midday may be given in small bundles, tied 18in. from ground. This ensures a bird exercising or going hungry. About 1oz. of wheat per bird, spread an hour before sunset, is sufficient in the evening. An hour before sunset gives the birds sufficient time to consume the food before roosting. *Breeding.*—If the standard efficiency of the flock is to be maintained, breeding must receive special care. Eggs for setting must be carefully chosen. No egg of less than 2½ozs. should be used if it can be avoided, neither should eggs from hens of doubtful pedigree be used. Any egg which is misshapen must be discarded; it shows some deformity in the bird producing it. Either natural or artificial incubation is effective. If, however, hens are used, see that they are free from parasitic diseases, and always place eggs on the ground. August hatched chicks should do best in this district, thereby providing a five-six months pullet to begin laying in February. The following points are essential to successful poultry raising:—1. A recognised strain. 2. Good accommodation. 3. Sound, clean feeding. 4. Careful breeding. 5. Rigorous culling.” (Secretary, Mr. R. Wilson.)

**PINKAWILLINIE.**—Meeting held November 1st, at the residence of Mr. E. Atkinson. Present: 16 members and a large number of visitors. Mr. H. Wheeler read a paper, “Fallowing,” from the *Journal of Agriculture*. (Secretary, Mr. S. Johnson.)

**SMOKY BAY.**—Meeting held November 18th. Present: 10 members and two visitors. The meeting took the form of a Question Box. (Secretary, Mr. K. Harrison.)

**EASTERN DISTRICT.****(EAST OF MOUNT LOFTY RANGES.)**

BOWHILL (Average annual rainfall, 12in.).

December 1st.—Present: 22 members.

**RURAL EXPANSION.**—The following paper was presented by Mr. J. Wallis:—"This subject covers a very wide margin, and the raising of 'Fat Lambs for Home Consumption and Export' comes within its scope. Owing to the very low prices offering for wheat the farmer inevitably has to look to his side lines and increase their production if he desires to balance his budget. The revival of the fat lamb industry will help the farmer very materially in this direction if worked on careful and economic lines." Extracts were then read from the *Adelaide Stock and Station Journal*. "Mate rams with the ewes in the proportion of one ram to 30-35 ewes. Rams well at work by mid-December will mean lambs dropping during the latter half of May, and they will be ready for market by the middle of September, three and a half months. Lambs marketed in November are far too late, bloom is lost very rapidly, and they become smothered in grass seeds. Lambs should not be kept any longer than possible. Once they start to go back in condition they soon become stores. Early feed is essential for the early fattening of lambs for market. To obtain this a good plan is to burn at least a portion of the stubble and sow it with an early variety of oats, preferably Early Burt, which grows quickly, has good foliage, and holds any tendency of the soil to drift. The chief point is the selection of the class of ewe most suitable for raising lambs in this district. I strongly favor a large-framed Merino, they are quieter than crossbreds and do not worry the fences. As regards rams, my selection is Border Leicester (1), English Leicester (2), Dorset Horn (3). The progeny of these, from Merino ewes, are in great favor with the butchers, also the export buyers; they are well set-up, nice frames, square built, and quick growers. Sheep and lambs are very susceptible to bruising if not very carefully handled when yarded or passing through gates, &c., this applies particularly to lambs. The poking with sticks is to be avoided, do not grab lambs by the wool, by so doing those for export are rejected on account of bruises. If a sheep is grabbed by the wool the latter is immediately injured and deteriorated in value. Catch by the hind leg with the right hand, keeping it low down, and pass the left hand in front of the forequarters, then the right to under the belly. By lifting the leg high the muscles and flesh are strained and become bruised, and in the case of lambs, are rejected for export. Drivers of transports conveying lambs to market must exercise great care with them, they are very tender, the sides of hurdles, &c., on transports should be padded. The 'Corriedale' is the coming sheep and it will considerably benefit the fat lamb industry. The breed is being kept true by the formation of a society."

A previous meeting held on November 17th was attended by 12 members, who inspected Mr. A. Just's crops of Gluyas, Ford, and Felix. Mr. A. Spry read a paper, "Farm Improvements." (Secretary, Mr. M. Banks.)

## BOOLGUN.

February 26th.—Present: 12 members.

**SCRUB ROLLING.**—Mr. E. Werfel read the following paper:—"The farmer's aim should be to get the land cleared as soon as possible. It does not matter how large the section may be, it is only the land that is cleared from which he obtains his living. Many farmers clear a few hundred acres and crop it until it becomes too dirty and worn out to grow a payable crop, whereas they could leave it for grazing, and clear more of the scrub land and be more sure of a clean crop. The best time to roll scrub is during June, July, and August; the sap is then "down" and the scrub breaks better. By rolling early it gives the shoots a better chance to grow before burning time. The best time to burn is late in February. If burnt too early one often has trouble with the shoots in the crop. Leave the scrub lay for two summers before burning. As to burning after the first summer, I experimented with a hundred acres. The portion that was in crop after laying for two summers yielded 50 per cent. more wheat, 60 per cent. less shoots, and 50 per cent. less snags than that portion which had only laid the one summer. Scrub rolling is heavy and rough work for horses, therefore see that the team is in good condition and well fed. Work the horses for half-days for a few days until they become used to the work. Do not try to pull down a tree or a clump that is too heavy for the team; it is better to nick these trees with the axe. Do not work horses when they become sore; it is better to spell them or put them on to some other kind of work." (Secretary, Mr. J. Palm.)

## KULKAWIRRA.

October 14th.—Present: 15 members.

**FARM BOOK-KEEPING.**—Mr. J. Kelly read the following paper:—"In these days of high costs of production and low prices for farm produce, it is of vital importance that farmers should keep proper books. Not only will a system of book-keeping show what profit or loss is being made in the farmer's various activities, it will also do away with that worrying and straining of memory when the income tax return is due. Keeping a record on the heel of the cheque book is very unsatisfactory, and, at the best, will only give the amount of cash available. How many farmers can definitely say that they cannot produce wheat for 4s. per bushel, or the exact amount of profit on the last pig sold? When entering your books it is a wise plan to remember that the three chief principles of book-keeping are—(a) The record should be so explicit and minute in detail that, at any subsequent time, the nature and character of the transaction may be readily perceived; (b) As the leading principle of book-keeping is classification, the transactions should be so classified that at any time the total results of such transactions, or of any particular class thereof, during any given period, may be readily ascertained. (c) The system of account keeping should be so devised that the maximum amount of information may be obtained, with the minimum of clerical labor. Three books at least are necessary for farm book-keeping—(i.) Diary, (ii.) Journal, (iii.) Ledger. In the Diary the daily work should be entered, together with any items of importance. This is the farmer's book of reference for such things as "when the sheep were dipped," and "what date the fallow was last worked." The Journal is known as the "book of original entry." In it should be posted, in full, all accounts. When entering this book it should be born in mind that memory plays no part in book-keeping. A Ledger is a book of final record, made up of accounts representing all the activities of the farm. From the trial balance drawn from it at the end of any period, statements of assets and liabilities and profit and loss can be prepared. The left-hand side of each page is for the entry of debits, and the right-hand side shows credits only. The difference between the totals of the two sides is the balance of the account. As all postings are made from the Journal, the folios should be indicated in the ledger accounts. In addition, I recommend that a "Paddock History Book" be kept. Once each year draw a plan of the block in it, showing the several paddocks, and color each paddock to show what condition it is in. For example:—Yellow for crop, brown for fallow, green for feed, &c. In one corner write any information of importance culled from the Diary, such as "date started and finished fallowing," "date started and finished seeding," "number of bags of wheat stripped," "number of tons of hay cut." In this way you will have the whole history of your farm at a glance. *Double Entry Book-keeping.*—As the name indicates—double entry book-keeping—the system in general use to-day—is based upon the principle that every transaction has a two-fold effect. Every sale, while it increases the cash, decreases the stock in hand. The payment of wages decreases cash, but results in an increase in services rendered. An equilibrium of accounts is maintained by equal entries for every transaction; a debit for every credit. Debits are shown on the left-hand side and credits on the right. It is often difficult to determine which account to debit and which to credit. The following principles may be stated as governing all business transactions:—(a) Debit the account with that which comes in; (b) Credit the account with that which goes out; for example:—Bought one ton of hay for £5. The account with hay receives the benefit of £5 worth of hay, and is therefore debited, the cash account suffers a corresponding reduction, and is therefore credited £5. The double entry system of book-keeping

affords a number of advantages that can be enumerated as follows :—(a) It provides for accounts representing every item of wealth possessed by the farm, and for every debt owed by the farm ; (b) It arranges separate classified accounts so that they disclose the expenses of the farm, the income, and the character of each class ; (c) It affords a basis for recording accurately the farm activities, the effects and results ; (d) By having equal and off-setting entries for each transaction it provides for an automatic check on the accuracy of the records ; (e) Double entry book-keeping also furnishes readily available information for statistical records. For those farmers who do not desire to go to the trouble of installing the double entry system, I recommend that they keep all their accounts under separate headings, such as "Horse Feed," "Fuel," "Repairs," "Machinery," "Wages," "Household Expenses," &c., and that they keep an account of all livestock transactions, natural increases, depreciation, &c. Pay all money received into the bank, and pay all accounts by cheque. (Secretary, Mr. H. Elliott, Karoonda.)

#### LOWBANK.

October 8th.—Present : 10 members.

**HARVESTER v. STRIPPER.**—The following paper was read by Mr. E. Koop :—The stripper is more suited to mallee country or any country that is sandy and hilly, it is lighter in draught and also saves more grain, it being very difficult to keep an even speed with the harvester while going over sandhills, this causes the seives to load and grain is often wasted. The stripper also has an advantage over the harvester in rough stumpy country. Owing to its greater weight and many working parts, the depreciation on the harvester is much greater. There is, of course, a considerable saving in labor by using the harvester, but this is more than off-set by the value of the cocky chaff, which can all be saved by using the stripper. Cocky chaff is a valuable asset in this district, and this has been brought home to us very forcibly during the last few seasons. It requires three extra horses in this district to get over the same area in a day with the harvester as with the stripper. Getting away from the mallee country where the land is firm and more or less level the harvester can more than hold its own with the stripper, owing to the big saving in labor and depreciation, also the cocky chaff is not so valuable there. Those districts are not so subject to droughts, and there is usually plenty of feed for the stock. A good supply of hay is usually cut, and the extra expense to save the cocky chaff is not warranted. The harvester also pulls at least a horse lighter in those districts as compared with our sandhills.

**BOOK-KEEPING.**—Meeting held November 5th. Present : 14 members and four visitors. A lecture was given by Mr. Armstrong, manager of Waikerie branch of the State Bank, on "Book-keeping on the Farm." In his address he pointed out the necessity for book-keeping in every business. Mr. Armstrong endeavored to simplify the method to suit the farmer, and deemed the single entry sufficient for the average man on the land ; otherwise, in its full sense, the double entry was the correct method. The speaker pointed out that the double entry was most reliable in business, but, as most farmers did not have time, the single entry recorded in an ordinary exercise book was sufficient, but the proper books to be kept for commercial concern to complete an up-to-date system were—Cash book, Purchase and Sales books, Journal, Ledger, and Petty Cash. Another necessity for books to be kept was, in the event of a proprietor desiring to dispose of his business, the first requirement of a prospective buyer would be to inspect the books. If there were no records of operations it was unlikely that any business would be done, for it was only on a knowledge of the operations that a buyer could decide what it would be worth if it was a prosperous one. Should one at any time approach a banker the first request would be for a statement of position. If this could be given from properly kept books, it inspired confidence at once. Expense could often be curtailed when income tax returns were due ; if proper records were kept the return could very easily be furnished by the farmer. (Secretary, Mr. L. Gayer, Waikerie.)

#### OVERLAND CORNER (Average annual rainfall, 10-50in.).

October 4th.—Present : 18 members and four visitors.

**QUESTION BOX.**—During the afternoon members inspected the crops and stock on Messrs. Loffler's property. In the evening the following questions were discussed :—"What size should paddocks be on 2,000 acre farms in this district?" Answer : After a good discussion it was generally thought if possible, to have paddocks from 50 acres around the homestead to about 320 acres further away. "Is it advisable to leave windbreaks?" Answer : All members agreed that windbreaks should be left every 30 to 40 chains, about two chains wide, and running north to south. "On what side of the break should the fence be?" Answer : Most members favored the east side, while a few preferred the west side. "Should white stemless thistle be destroyed?" Answer : These were thought to be harmless, and would provide feed for sheep in time of droughts. "Can we successfully grow wheat at present day prices ; if not, why carry on?" Answer : All were agreed that this was impossible with wheat at its present price (below 2s. bushel on river bank). The chairman remarked that no business would carry on if it could not make it pay, but members all agreed that the farmer had no alternative but to carry on. "What is the best harvesting machine for this district?" Answer : The two members who spoke on this question were of the opinion that anyone cropping upwards of 600 acres should have both stripper and harvester. (Secretary, Mr. H. Loffler.)

November 4th.—Present: 12 members.

**FODDER CONSERVATION.**—The following paper was contributed by Mr. G. Chesney:—Farmers generally, and mallee farmers in particular, have many things to contend with during the course of each year's operations. There is nothing, however, which causes greater concern than the want of a sufficient supply of feed for his stock during dry periods when feed in the paddocks is scarce or non-existent. It is, therefore, most important that suitable provision should be made to meet such circumstances. We have passed through one of the most devastating droughts in the history of this State and probably for the whole Commonwealth. The effects of such droughts to farmers are very disastrous under any circumstances; but, when little or no provision has been made to conserve feed, it is a calamity. Australia is subject to these dry periods, so that it is natural for us to expect such visitations in the future, and make provision accordingly. Before making a few suggestions in this direction I desire to refer to some facts on food values, Bulletin No. 153, Department of Agriculture, "Cereals and Cereal Hay." The relative merits of oats and wheaten hay is not infrequently a subject for debate at Bureau meetings, and those accustomed to feeding horses with good, sound wheaten hay are loth to believe that any other fodder could replace it with advantage. Notwithstanding the many valuable properties of wheaten hay, the outstanding qualities of well-saved oats hay must place it in first position. Apart from the fact that chemical analysis and digestion trials combine to give it a higher value to the extent of 10 to 15 per cent., there is, unquestionably, some principle peculiar to the oat plant which has an exciting and stimulating effect on the animal system, and this in itself is sufficient to warrant a preference for oats hay whenever a choice can be made. For dairy cattle, oats hay is better than wheaten, as it appears to encourage milk secretion to a greater extent, and, when fed in the sheaf to cattle or sheep, there is less waste. Oats are unsurpassed as grain food for horses and ruminants, and, fortunately, in normal times they are relatively cheap. The high percentage of digestible fats which they contain makes them particularly suitable for animals that are required for heavy draught or fast work, and the stimulating influence of the husks on the bowel walls aids digestion and assimilation. New oats should be fed with care as they are apt to cause colic. When they are 10 to 12 weeks old they are usually safe; but, if delay is impossible, the laxative effects may be reduced by mixing with salt and exposing to the air for three or four days. Cocky chaff consists of husks of grain, together with portions of the straw and leaves, inferior grains, weed seeds, and rubbish. On the whole it is more valuable than straw weight for weight, and is generally better appreciated by stock. Like straw, it is low in nutrients and rich in fibre. Oaten cocky chaff is the richest, and that obtained from beardless barley comes next, and then wheaten. The foregoing facts should be helpful in considering the problem of feed conservation. Most writers that I have read on this subject stress the importance of ensilage, and I have not the slightest doubt about the merits of such a method of conserving feed, provided, of course, that the district is suitable to that method being applied economically. Such would not be the case in light mallee country. One of the simplest and most economical means of saving feed is in the paddocks—natural pastures. How many farmers give this matter the consideration it deserves. Compare the difference in the stock-carrying capacity of a paddock which has just been left out after a crop of wheat that had a fairly liberal dressing of super with one that has been left to grazing for some years, the difference is most apparent. A great deal could be done in this direction, and to leave out a paddock for pasture, there should be the same consideration and forethought given as in the case of wheat or any other crop. To get the best results, grow a crop of wheat off fallow, using a liberal supply of super, followed by a crop of oats with another dressing of super. Left out to grass in this way, it will be surprising the amount of feed that will grow in comparatively dry years. I recommend cutting some hay each year, when possible: sufficient for the purpose of seeding and fallowing, keeping for reserve oats and cocky chaff. To keep hay for any length of time, either loose or in sheaves, requires a lot of protection, not only from mice, but against fire. There is one method of keeping hay which appeals to me, and that is to bale it. It would be much safer from destruction by mice, and opens up much fresher and better feed. It would not be necessary to use a binder when cutting, which is an advantage in rough country. Baling would be an ideal method of conserving straw. Oaten straw should always be cut or logged, raked up whenever possible and put in a stack, it will be found a valuable standby in times of drought. Oats should be grown much more extensively than at present is the case in this district for several reasons—1. If sown early, they make good pasturage for several months when grass and other herbage is scarce in the paddocks. 2. They can afterwards be reaped at harvest time, supplying one of the best grain feeds procurable for horses. 3. They improve the land, not only as a feed paddock, but the grass immediately following the next wheat crop will also benefit. Cocky chaff should never be wasted. However, to store in sheds all the chaff that would be taken off in a good season would require a great amount of space, more by far than many of us could make provision for. For that reason, I suggest a method which will cost little more than the work of erecting it and conserve the chaff in perfect condition for years. The first thing to consider is a suitable position; find a place where there is not a lot of loose sand and in a sheltered position, then proceed with the erection of a netting wire enclosure, size according to your requirements. Height should be not less than 8ft. or 9ft., and the posts leaning outward several inches to keep rain from running down the sides. When filling the enclosure, pack the chaff firmly, raising it well above the top of the wire. It can then be left to set for a time before covering with a good coating of straw. Use a few lengths of plain wire to secure it from blowing up with the wind. To use sticks for this purpose will cause rain to penetrate the straw. Oats are the best of all

feeds which can be grown profitably in this country, both for storing purposes and for use at all times. Fed with cocky chaff there is no other method of feeding horses to compare with it if the proper quantities are given. Not only is it an easy way of feeding horses, which is a consideration in busy times, but there is always much more life and stamina in horses fed on oats than there is with any other feed which we grow. Oats have a greater attraction for mice and other pests than most other grains, and to keep them for any length of time in bags is asking for trouble. To overcome this difficulty I suggest the erection of silos, which appear to be the only solution of the problem. Almost any handy man could erect a silo of corrugated iron to hold several hundred bags of oats, which would cost very little more than the price of bags, and then it is there for all time. It could be built either on the ground with a cement floor or it could be elevated. Having it elevated would enable one to use a spout for the purpose of emptying. Either principle would be much superior to bags, and, in the long run, would be considerably cheaper. *The proper and judicious use of such feeds as we have on hand.*—Most of us within the last three years have been in the unfortunate position of having to buy feed to put in the crop, and I venture to suggest that in every case the feed was measured out with care and judgment. Are such methods applied when cocky chaff is being used? I do not think so, and that is a very grave error, because feed is wasted by giving more than is necessary. When there is an abundance of cocky chaff the mangers are kept full. Use the same care and judgment as in the case of chaff which has to be bought. You will not only save feed, your horses will do much better. (Secretary, Mr. H. Löffler.)

#### RENMARK (Average annual rainfall, 10.52in.).

Meeting held November 13th. Present: 11 members and six visitors, Mr. F. Ferguson delivered an address, "The Case for the Queensland Sugar Grower." (Secretary, Mr. W. Meier.)

November 14th.—Present: 12 members and two visitors.

Mr. H. Milner delivered an address, "Fodders and Their Value for Pig Feeding."

**DIPS FOR SULTANAS.**—The following report of a Conference held at Mildura to discuss the subject of "Dips for Sultanas" and the progress that the district has made towards supplying the requirements of the London market was given by Mr. R. Howells at a meeting held on December 11th. *Circumstances Leading up to the Conference.*—For many years the boiling caustic dip met all requirements of the various markets our fruit was sent to; then came the demand for light colored fruit. The experiments of different growers and groups of growers with dips of all descriptions immediately caused chaos in the various packing sheds. Fruit of light color down to samples which have been referred to as "spotted dog" came forward. This state of affairs made our position worse than it was before on the overseas market. Then came the typing of the different colors which made for a large number of lines of fruit, which did not lend themselves to profitable marketing. The packing organisations then turned their attention to blending the various types within the grades in an endeavor to secure the long lines of fruit so desirable on the overseas market. This system was necessarily expensive. There came into being the classer at the shed door and the costly machine used for blending the fruit before passing it through the grader. In some districts the blending of the fruit has been very successful, others the reverse. Our pack last year stood out, both for quality of fruit and a high standard of packing, never before reached in the history of the companies' operations. Last season the efforts of growers in putting forth such an endeavor to produce a high quality sultana is worthy of the highest commendation. Our pool pack for sultanas on the London market this season has received the highest prices paid, and, furthermore, we are receiving our full share of sales. Growers, despite the gloomy outlook, stuck to their guns, and, generally speaking, achieved a splendid result. Despite the pessimistic utterances of some men, do not be disheartened, still strive after a quality sample, and we will carry on where others are going to the wall. Follow up your efforts of last season, and we will produce the goods in the best possible manner. We are keen on keeping up the good reputation made for our pack last season. Despite the shed's efforts at blending, and we had lines of different types ranging into hundreds of boxes, the doubt exists whether we are working on right lines. What will happen if the blended fruit has to be kept a long time before it is sold? Just about every grower has his own ideas on dipping sultanas and with the innumerable formulas being used, what will be the result when the fruit has matured by months of storing in different temperatures? Will the blend retain the color as when it is packed? I am certain that it will not, for the different chemicals used at different strengths will alter the color of some of the berries; some will undoubtedly go darker, and when the fruit is opened up for sale, the line will not be true to the type marked on the outside of the box. This contention has been proved by different sheds, and it seems necessary to standardise dipping methods, and for this reason the Mildura Conference was held. *Uniform Dip.*—In opening the discussion, Mr. Howie said that packers should approach the Conference with the view in mind that

the dried fruit industry was too big to develop piecemeal, and it would not get anywhere as an export industry, if they did not get together and pool knowledge for the good of all. Mr. F. Arndt (South Australian Department of Agriculture), Mr. A. Lyon (Department of Science and Industry), and Mr. R. Voullaire (of Merbein) then gave interesting expert information on the use of the different dips. Mr. Cleary (Aurora) spoke with reference to the Harry Johnson dip, stating that so far as the 1929 pack was concerned 70 per cent. of the fruit so treated had turned out four and three crown quality. Messrs. B. Haynes, W. Pardy, A. Ingerson, P. Malloch, and several other delegates also spoke on their experience with the different dips. After much general discussion it was resolved that a committee be formed with a view to bringing in recommendations to this Conference. Committee appointed was Messrs. Seary (convenor), Haynes, Palmer, Howells, Malloch, Lyon, and Arndt. Recommendations of the committee:—1. "That in the light of past experience three standard dips are sufficient for the Australian industry and that more are undesirable. The variations in dips devised by individuals or small communities have resulted in a multiplicity of types without any compensating advantages; increased cost of production, and increased difficulties in marketing." 2. "That the three standards recommended by the Conference of packers in consultation with Messrs. Lyon and Arndt are:—(a) cold dip; (b) modified hot caustic dip; (c) mixed dip. That practical experience of the industry, confirmed by the research work, indicates that the cold dip and mixed dip give satisfactory results only when the condition of the fresh fruit is satisfactory and drying conditions favorable, therefore, in the interest of standardisation, it is strongly recommended that the modified hot caustic dip be recommended for general use. That this Conference request Mr. Lyon, after consultation with the Department of Agriculture in the States concerned, to prepare an advisory pamphlet descriptive of the preparation and use of these standard dips."

#### WAIKERIE (Average annual rainfall, 9.6in.).

February 13th.—Present: 17 members.

**HARVESTING OF SULTANAS.**—Mr. H. Beriman (District Horticultural Instructor), in an address on this subject, dealt with the factors which, apart from dipping, were primarily responsible for much of the low-grade fruit. The time to begin picking was more or less governed by the amount of rack space. In any case, picking should not begin until the grapes showed a Beaume test of 13 per cent. If they were picked sooner the loss in weight was too great. He had set a Beaume reading of 13 per cent. as a starting-point, but this could be taken as a guide only, as the maximum Beaume obtainable showed considerable variation on different vineyards and in different seasons. During recent years the chief purpose of the grower had, or should have been, to produce quality fruit, and the difference in the values of the various grades was a big incentive to spur him on to that end. Of what value was correct cultivation, irrigation, fertilising, and dipping if one had not sufficient rack space to handle the crop. In all the settlements he found growers working right through the year using all the knowledge they possessed in order to produce a heavy crop of sultanas, and very often they achieved their purpose, but if there was not sufficient rack space to handle it, the labor and cost of producing it was very largely lost. Most of the one and two crown sultanas were traceable to either uncovered racks or a shortage of rack space. (Secretary, Mr. R. Thompson.)

**YOUNGHUSBAND.**—Meeting held November 5th. Present: Mr. G. Mann (chair), seven members, and two visitors. Mr. Mann read an instructive paper, "Side Lines on the Farm." (Secretary, Mr. H. Gowling.)

**SOUTH AND HILLS DISTRICT.****ASHBOURNE.**

After having been in recess for some time, meetings were resumed on October 23rd. There was a good attendance of members and visitors, and addresses were delivered by Messrs. H. C. Pritchard and H. J. Apps of the Department of Agriculture.

**LICKS FOR SHEEP.**—Meeting held November 5th. Present: 12 members. Mr. M. Horwood addressed the meeting on "Licks for Sheep," the former part consisting of the reading of an address by Mr. Marston, the chief of the Division of Animal Nutrition, delivered at Mount Gambier. This was supplemented by an original paper embodying Mr. Horwood's experience. It was stated that for wool growing a lick containing cystine was necessary, as this substance was present in wool to the extent of 13 per cent. Legumes, such as clover, were deficient in cystine, and did not provide an ideal wool-growing diet. Top dressing did not pay on land with less than 20in. rainfall, but some of the benefits of top dressing could be achieved by feeding phosphate in lick form at a very small cost. Iodine was present in sufficient quantities in practically all Australian soils, therefore a lick containing iodine was not necessary. A lick Mr. Horwood used was mixed in the following proportions:—100lbs. rock phosphate; 100lbs. salt; 6 per cent. molasses. One sheep would require 4lbs. to 5lbs. per annum, and the cost would be roughly 2½d. per head. Members stated that they had found rock salt to be very much liked by sheep, but that was practically their whole experience as regards licks. It was surmised by some that a lick for wool production might not be the most suitable for fattening purposes, but the speaker, while agreeing with this, said that the lick he was using (above referred to) had improved the health of the sheep, and healthy sheep would grow more wool as well as fatten better.

**BANKING AND FINANCE.**—Meeting held December 3rd. Present: 10 members and six visitors. Mr. F. Laycock, Manager of the Strathalbyn Branch of the National Bank, in the course of an address on the above subject, said banking and finance were matters which it was necessary at these times to understand more fully than had been done in the past, and that individuals should take a more active part in determining the management of the affairs of the nation was the hope expressed. The functions of a bank were to trade in money as a merchant trades in goods. The margin between interest paid on deposit and interest accruing from loan represented the profits to the bank in the same way as a merchant received a margin on the purchase and sale of goods. The advantages of a bank were mainly:—(1) To provide a safe depository for funds; (2) to save time and trouble; (3) to facilitate the payment of debts; (4) to lend on overdraft; (5) to provide safe keeping for deeds and securities; (6) for reference. Among the functions of a bank was the issue of notes for currency. This, however, in Australia was all done by the Commonwealth Bank. The issue of notes in lieu of coinage multiplied the usefulness of currency. The coin reserve was about 33½ per cent. of the note issue, and this proportion was looked upon as perfectly sound policy. As, however, all notes issued were not in circulation, the proportion of coinage was slightly greater than the above. The value of life assurance was emphasised, the speaker saying that in the institution with which he was connected it was necessary for employees to take out a policy to supplement the existent provident fund. That farmers, in common with other businesses, should take stock at least once annually was also expressed, as this enabled a more accurate survey of the operation of the business. In this connection, it was also stated that it is wise for a customer to acquaint his banker with the state of his business, as this established a feeling of confidence and facilitated business. In selecting a bank, care was necessary, although in Australia any one of the associated banks was quite safe. With regard to the all-too-much talked of repudiation, it was made apparent quite safe.

**POTATO CULTURE.**—Meeting held January 28th. Present: 10 members. In the course of an address on the above subject, Mr. C. Pitt said that his intention was to deal more particularly on the care and selection of seed. The potato was second to wheat as a staple food, and therefore commanded a great deal of attention. The prevalent idea that imported seed gave better results than local was because local seed, as a rule, was the culls after the marketable tubers had been disposed of. The speaker's experience in this matter was that, after a number of years' saving from his own crop, the results were in no way depreciating; in fact, the reverse was the case. This, however, was the outcome of selecting the seed as the crop was dug, when any good plant would be put aside and saved for seed. Another point stressed was the advisability of planting seed dug before the crop was quite mature. The results of various authoritative experiments proved conclusively that immature seed gave better returns than that dug when the haulms were dry. The opinion that cutting the seed up to 24 hours before planting did not adversely affect it, provided it was not exposed to the sun, was expressed. An alternative to farmyard manure was the practice of ploughing in such green manure as peas, mustard, and rye. This enabled the soil to retain its original

character and productiveness. Mr. V. Payne, in the following discussion, stated that he found the stem end of the seed potato inferior to the other end. He favored a change of seed for early planting, at any rate with Snowflakes. He obtained the best results by importing seed each year. Mr. W. Carter stated that scab was prevalent before the advent of super. The opinions as to manuring were that super with potash in quantities not above 10cwts. to 15cwts. per acre of the mixture was preferable. (Secretary, Mr. H. H. Pitt.)

March 4th.—Present: 14 members.

FODDER CROPS.—Mr. V. Payne read the following paper:—"Many farmers now recognise that they must keep the maximum amount of stock to enable them to obtain the greatest possible yields from their holdings. It is questionable whether this is being done, especially in our southern or heavy rainfall districts, owing to the fact that special crops for fodder are not being grown. Since the decline in prices for all our products of from 30 to 50 per cent., a serious review of our primary production must take place, to enable us to obtain a greater net return. There is food for thought in the fact that as a rule we find the winter half gone before the stock are able to get sufficient green feed. Fodder crops could be grown to fill this gap. These could be divided as follows:—First and best, lucerne; second, peas; third, oats; fourth, maize and others. The feeding value of lucerne is well known, but unfortunately the flea is a serious pest. The best time, generally speaking, for sowing in this district would probably be late August and September. If the seed bed is well prepared, a heavy sowing of seed, say, 20lbs. to 25lbs. per acre, applied, and as soon as the plant was strong enough, to be cut, the effects of the flea would certainly be lessened. With irrigation four or five cuts could be obtained during the season after the bed had been established. Lucerne can be fed with a big profit to dairy cows, ewes and lambs, and breeding sows. If fed in conjunction with oatens chaff and bran, there is probably no more suitable ration for a dairy cow. It is usually recognised that 1 acre of lucerne, well irrigated and manured, will produce enough green feed during the summer months to keep from seven to ten dairy cows, if fed in conjunction with the necessary dry feed. Peas fed dry are probably one of the best fattening grains. Pigs have certainly not received the attention they should in this State. Usually they are regarded as a side line of a dairy farm. This, to an extent, is true. The skim milk is a great aid in fattening and rearing young pigs. Pigs are a paying proposition on almost any type of farm. I have already quoted lucerne for breeding sows and little pigs, and to follow this up with a good paddock of peas would be a very reliable and profitable practice. The lamb breeder, also, is able to take advantage of the pea crop, selling the lambs at from 11s. to 13s., instead of at from 6s. to 8s. for grass grown lambs. Ewes and wethers can also be fattened on peas profitably. The practice of sowing oats for early green feed, especially on the better lands, has probably no equal. To sow oats on land cropped by potatoes after the first autumn rains is unquestionably good. Best results cannot be expected from land freshly broken up, as so much more rain is required to render it fit for sowing. Two to 2½bush. is the best amount to sow. Some farmers advocate drilling both ways, in order to obtain a better plant, and reduce subsequent damage by stock, principally sheep. The oat crop can be grazed off until August, and a good hay or grain crop obtained. This is in the nature of obtaining two crops at once, first the green fodder and then the grain. Oats are an excellent cover crop for subterranean clover. Maize is principally used by dairymen. Probably a greater amount of fodder per acre can be grown from this crop than from any other. September and October are suitable months for sowing, and swampy land is preferable. The growth is prolific, as is also its soil-impoverishing tendencies. Maize may be used as ensilage or fed to cows with chaff and bran. Fed in conjunction with the natural grasses only, it is not a profitable crop. Barley is a splendid early feed, but has not the staying powers of oats, nor has it the same value for hay. It is a really good fattening grain. Turnips and rape are also good fodder crops, being splendid for sheep and pig grazing, both being easily grown on good soils. On our good lands a good rotation of crops would be:—First year, natural grasses; second, peas; third, potatoes, turnips, or rape; fourth, green feed, oats, &c. Land worked in this way will not run out, but will produce good crops year after year, under favorable weather conditions." An extract from a publication on Sudan grass, to the effect that it was a rank feeder, was similar in composition to Johnson and other similar grasses, was a laxative, was drought resistant, and under good conditions produced more hay than any other crop, completed Mr. Payne's paper. Mr. H. B. Meyer considered that lambs did better in paddocks where subterranean clover is not so plentiful, i.e., where rye and other grasses of that kind predominated. Messrs. Kirkham Brothers had proved that clover was a pronounced success on second-class land. It was readily agreed that lucerne was the "King of fodders." (Secretary, Mr. H. Pitt.)

## BALHANNAH.

November 7th.—Present: 18 members.

Mr. W. J. Spafford (Deputy Director of Agriculture) gave an address, "Manures."

At the meeting held on December 5th, which was attended by 14 members, the Secretary read a paper, "The Apple and its Cultivation." (Secretary, Mr. C. Grasby.)

## CURRENCY CREEK.

November 10th.—Present: 12 members.

THE DEPARTMENT OF AGRICULTURE AND THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.—Mr. E. Skewes read the following paper:—The Bureau was established in South Australia in the year 1888, the first meeting being held on April 10th in that year. At the close of the first year, the membership roll contained 53 names, and the number of Branches then in existence was five. Those figures have since increased very rapidly, and there are at present 8,337 members and 305 Branches, a truly remarkable record and an indication of the widespread nature of the Bureau. The number of new members enrolled for the last financial year was 610, and the number of new Branches established for that year 26, which shows that there is still room for expansion, and also that in spite of the hard times we are now experiencing, the Bureau is continuing to make very satisfactory progress. During the year 1912 it was decided to confer life membership on those members who render services to the Bureau that are worthy of special recognition. There are at present over 280 such members. It is usual that this distinction should not be made until a member has been connected with the Bureau for at least 20 years. Membership of the Bureau contains a number of privileges and facilities for the obtaining of information of value to those engaged in primary production. The services of the Departmental officers are at all times available to members, and the District Instructors are always glad to have the opportunity of looking over a member's farm and offering such member any advice he may require during the time that the Instructor is in the district. By having the Instructor on the holding, he is in a much better position to advise the farmer, as he can more readily ascertain the exact nature of the difficulty and the circumstances contributing thereto. A visit of this nature is most interesting, and that apart from any actual trouble that the farmer may wish to discuss, he will find a general talk on his farm with the Instructor very beneficial. Our Branch has had some very interesting addresses delivered at our meetings by the Department's Instructors. The Department is at all times ever ready to assist members in any way possible. A letter addressed to the Department will be attended to promptly and a complete answer given to the queries contained in same. The Department is also prepared to analyse, free of charge, samples of water and soil and ascertain the proportions of chemicals, &c., contained in them. Although, as mentioned previously, the Bureau section is what interests us most, we must remember that the Department is in charge of a tremendous amount of work in the way of experiments and research work, and on which the value of the Bureau is really based. The Department has under its control two experimental farms—one in the South-East and Lower North, and experimental orchards at Blackwood and Berri. In a further endeavor to ascertain the individual requirements of various parts of the State, the Department has established demonstration and experimental plots in various centres on private farms in association with the local Branches of the Agricultural Bureau. These plots, whilst proving which grasses and cereals are most suitable for the particular district in which they are located, are also used for superphosphate experiments, and are of considerable benefit to farmers in these districts where they are situated. Roseworthy College and the Waite Research Institute are closely allied to the Department. In Roseworthy College an opportunity is afforded to the students to gain an insight into the practical side of agriculture, and farmers' sons on leaving school have the chance of studying whichever branch of primary production it should be their intention of pursuing later in life. A Winter School is conducted at the College each year for a short period, and an invitation is extended to anyone engaged in agricultural pursuits to attend, members of Agricultural Bureaux having preference. Besides the instruction section, the College does a lot of experimental work with the breeding of new wheats, the breeding of lambs suitable for export, and the State owes a good deal of its success in farming to the College. A number of competitions are conducted by the Department each year throughout the State, and they now comprise such competitions as fallow, crop, seed wheat, improved pasture, farm, and pruning. Valuable prizes are presented to the Department by manufacturers, vignerons, and others interested in the welfare of the competitions, and, although it is not many years since they were first started, they have become very popular and are well contested. Several field trials are conducted each year, at which farmers are given the opportunity of comparing the various farm machinery at work under local conditions. The Department is indebted to the machinery warehouses for the interest they take in these trials, as they are often involved in considerable expense in making available their machinery. A number of Branches of the Women's Bureau have been formed during recent years. The first one

was established at Riverton in 1917, and since then similar Branches have been formed at Saddleworth, Williamstown, Kalangadoo, Millicent, Pinnaroo, Wilkawatt, Kangarilla, Wasleys, Belalie, Gladstone, Auburn, Goode, Eureka, Millicent, Nelshaby, Parrakie, Wirrilla, Parilla, Parilla Well, and Warcovie. These Branches are conducted on similar lines to those of the men, and have been found a very advantageous introduction. Another important section of the Department is the Library and that dealing with the issuing of literature and the *Journal of Agriculture*. The Library is available to members in search of some particular information, and with a view of bringing that portion into closer touch with the farmer, a number of Branches have started libraries of their own. A number of bulletins are available from the Department, and a list of them will be found on the back of any *Journal of Agriculture*. A member requiring information on a special subject would be well advised to obtain one dealing with the particular matter in which he is interested. The *Journal of Agriculture* contains much useful information, and a half-hour can be spent very profitably in reading it through.

The officers of the Department are in constant touch with similar organisations in the other States and in various parts of the world, and is regularly receiving valuable information from those sources. The Department of Agriculture in Victoria recently introduced the Better Farming Train system into its activities, and our State was particularly fortunate in being granted the use of the train for a short period. A very large number of farmers availed themselves of the opportunity to visit the train during its limited stay, and a great deal of interest was evinced by them in the various exhibits and lectures. The fact occurred to me how desirable it would be if such a train could be made a permanent institution and a visit made to the whole of the agricultural areas of the Commonwealth. Unfortunately, on account of the variety of railway gauges with which our country is beset, that is practically impossible. Australia is mainly dependent on her primary products, and it is unfortunate that only a small proportion of the population is engaged directly in rural pursuits—the proportion in this State being about 10 per cent. of the total population. On account of this fact the primary producer is at a very serious disadvantage, since in all things, Government and otherwise, the majority rules. It seems to me that the man on the land is not always regarded in the kindly light that he is at such times as we are now passing through, when people more than ever realise what an important part he plays in the national welfare of our country. I trust that not only now, but also when good times come again, the primary producers will receive the utmost consideration and encouragement that they undoubtedly deserve and which it is their right to expect. It is through the Department of Agriculture that we must look for a helping hand, and it will be through the recommendations of the Advisory Board of Agriculture that our requests and requirements will receive the most respect. We do not only need the assistance necessary for increasing our returns, but also the means of remedying those influences that are operating against the primary producer, and are preventing the business of primary production being carried on profitably. The low prices ruling for our marketable produce would not affect us so adversely if it were within our power to regulate the costs of production accordingly. With the Advisory Board of Agriculture and the Department of Agriculture there is a connection from the farmer to the Government in matters of legislation due to his membership of the Bureau. In this connection, the District Conferences of the Agricultural Bureaux and the Annual Congress, which is held in Adelaide, are valuable as a means of passing resolutions for the improvement of legislation affecting the man on the land. One of the main objects of the Agricultural Bureau system is to forge a connection between the Department of Agriculture and the primary producers, whereby the latter can be informed of the results of the Department's activities. Another advantage of the Bureau system is the social side. It is of considerable value in that respect, for by meeting each month, the residents of a district are brought together and given an opportunity to exchange ideas and discuss matters of local interest. Our Branch was started in 1922, and I feel sure has been of very great assistance to those connected with it. I sincerely trust that it will continue to progress and that the ensuing year will be a very successful one.

Meeting held December 8th. Present: 13 members, two visitors. Mr. R. Tavener read a paper dealing with a trip to the Marrickville (New South Wales) Woollen Mills. Nine members were present at the meeting held on January 12th, which took the form of a Question Box. To poison boxthorn, Mr. Shipway was advised to use a solution consisting of 1lb. of arsenic to 10galls. of water. (Secretary, Mr. D. Gordon.)

MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).

November 4th.—Present: Seven members and two visitors.

PIGS.—Mr. R. Wheaton read the following paper:—"Pig raising on the Island is a side line that should receive more attention than it has in the past. The food can all be easily grown on the farms, and if carefully attended the pigs should show a good profit over a number of years. The prices received for pigs—as with any other

stock or produce—will vary, so that it is necessary to compare high and low prices. The successful pig breeder is the man who sticks to his job, and although he will experience times when profits are small, it is safe to assume that prices will rise again. While I have found the Mid-York to give good results, the question of breed is one of opinion, but if pigs for export are to be successfully raised, more consideration will have to be given to the breed that suits the market where the bacon is sold. As the distance from the market has to be considered, it is most profitable to market pigs from the Island as prime baconers, weighing 120lbs. to 140lbs. dressed. It is not advisable for a beginner to start with too many pigs. One or two sows for a start, and if they are good ones, the sows from them can be kept as breeders, but it will be found that, unless a lot of milk is available, four sows are enough for a farm. Having selected the sows and boar—which should always be a pure-bred one—they can be mated at about eight months old. A sow will rear two litters a year. Care should be taken that breeding is arranged so that they do not farrow in the hot months of summer or the cold wet of winter. The question of sties has to be considered, and while makeshifts can be used to start, the sooner one gets good sties with a good floor, so that they can be easily cleaned out every morning, the sooner will a bigger profit be shown. There will be less losses at birth, the general health of the pigs will be better, and the stock easier to handle. About four sties are necessary for farrowing and topping up pigs for market. There should be two compartments—the inside, which is roofed and is used for a bed, should have a rail all round about 7in. from wall and floor to prevent the sows lying on the young pigs, and the outside portion for feeding. If built of stone or concrete, a concrete trough can be cheaply built in. Besides the sties it is necessary to have a few small paddocks of  $\frac{1}{2}$  acre to 1 acre with a shelter in each. These can be sown for greenfeed, or after they have been used for pigs for some time, will grow quite a lot of grass. Naturally, the pig is a grazing animal, and a good supply of greenfeed that can be grazed is a good help for the boar and sows, and the young pigs after they are weaned and until they are shut up to fatten. There is no animal that turns its food into a saleable carcass so rapidly or efficiently as the pig, and while 4lbs. of barley to 1gall. of skim milk makes an ideal ration, other foodstuffs can be made use of. It is for the individual farmer to use the material he has or which he considers he can most economically provide. I consider barley the cheapest food that can be grown, with oats and peas when they are available. The sows and boar can be kept in a small paddock most of the year, and besides grass and plenty of water—which should be available to pigs at all times—I consider sheaved barley the best other feed for them, with oats for a change. They eat some of the straw and always have bedding. Sows should be brought in to the sty a week before farrowing and fed on swill—milk and soaked barley. Give the sow a bedding of straw, but do not have a lot in the sty at farrowing time, and it should be short. A sow can rear eight pigs comfortably, but if more than nine she will need a little extra attention, with the best food should rear a good, even litter. At four or five weeks the young boars should be castrated and weaned when about seven weeks old. At four or five weeks the young pigs will start to eat, and can be given a little crushed barley and skim milk where the sow cannot get it. At weaning time turn the sow out and leave the little pigs in the sty for two or three weeks longer. They should be well fed, but should not be given more than they will clean up. If any food is left remove it before putting in a fresh feed. Before turning out the sow, give her an oiling with waste oil. If it is put along the back it will soon run down over her body. This keeps the skin clean and free from scale and vermin. The young pigs should also be oiled before they are put out in the small paddock from the sty. If there is green grass or other greenfeed available, the pigs will not need so much grain to keep them growing well. It is at this time that one can force the pigs or just keep them going so as to market when at the most opportune time. No doubt crushed grain is better, but pigs do well on soaked, and saves the expense of crushing. A certain amount of crushed corn is much better while the pigs are small. Where there is not enough milk, meat meal occasionally is necessary. Wallabies or kangaroos boiled, and, when cooked, added to the barley make a good feed. A little bone meal mixed in with the feed is a help. Charcoal and any ashes available should be put in the pigs' yards. When the pigs are grown—fit to top up—they should be brought into the sties. Do not put too many together in a pen—three or four is sufficient. If you have more than the pens will hold at once, pick out the biggest and get them off to market and then bring in the seconds. As soon as they are penned spray them with milk oil fluid to get them clean, and repeat this about twice—the last spraying a day or two before sending to market. An orchard spray is a good thing for this. When fattening give as much feed as they will clean up. Brand the pigs with a letter by painting after first cutting the hair where the letter will be. Always send pigs to market as a good even line, so that of, say, 12 pigs, they will only need to be divided into two lots at the most for sale. Quality is the main factor to aim at. Always see that the pigs are in prime condition before marketing. There is room for a good deal of co-operation by two or more pig raisers who own three or four

sows. If they agree on the breed, one boar would do for both. They could also market together, so that a full load could be taken in, and also be a full load for a carrier at Port Adelaide. In conclusion, do not show a lad the pigs and the feed and expect, without any further attention, to find prime pigs ready for market in a few months time. Pigs deteriorate quicker than any other animal, and the owner needs to see them often, and if not doing well, remedy the fault. Healthy stock bred and kept in clean, warm, healthy sties, and fed regularly will give regular and rapid increase in value, brought about as economically as possible. If this cannot be done, do not keep pigs." (Secretary, Mr. J. Wood.)

#### MOUNT PLEASANT (Average annual rainfall, 27.29in.).

December 5th.—Present: Eight members and 27 visitors.

**BUSH FIRES.**—The following are extracts of an address delivered by Mr. Geo. Warren, of Mount Crawford:—Everyone should have some appliance to combat fires. When a fire is put out, make certain it cannot break out again. It should be the duty and in the interest of every good citizen (not only landholders) to prevent fires. The public should be educated to the dangers of bush fires and to take precautions. In Mount Crawford district, steel fireplaces are erected on picnic grounds, where warnings are posted up. On Saturday afternoons, Sundays, and holidays voluntary patrols are engaged, who have power to enforce the Bush Fires Act. Round-shouldered clear glass bottles can cause a fire, so should be destroyed. Helpers should be directed where to go. Make sure everything is out on the night of the fire. Mr. Davey then spoke to the meeting about knapsack spray pumps: he urged everyone who possibly could to possess one, which would greatly minimise the risk of fires spreading. (Secretary, Mr. D. S. Smith.)

#### PORT ELLIOT (Average annual rainfall, 20.02in.).

The monthly meeting was held on November 21st at Mr. A. M. Fuller's property, at Inman Valley, and was attended by 19 members, together with members from Inman Valley and Rapid Bay Branches, Messrs. R. C. Scott and R. Hill, of the Department of Agriculture, and C. A. Goddard (Wool Instructor, School of Mines). The meeting took the form of an inspection of the experimental plots of Mr. Fuller's property.

February 21st.—Present: 16 members.

**DRIED FRUITS.**—In the course of an address on this subject, Mr. J. Foot emphasised the value of dried fruit in the home, both from an economical and a health standpoint. Nearly all farmers had fruit trees of some kind, and any outlay that was made so that the fruit could be dried would be well repaid. Only the best quality should be used and in the best condition. If possible, trays should never be made of iron or bags; the most convenient size was about 4ft. x 2ft. Apricots should be sulphured for 10 to 12 hours, with about 1lb. of sulphur to about 60lbs. of fruit. Plums in many cases made just as good dried fruits as prunes. Use a hot caustic dip for these fruits (1lb. caustic soda to 10galls. boiling water), and leave the fruit in for 8 to 10 seconds, with a little longer if the fruit is green. Best results will be obtained with prunes if drying is started in the shade in a position so that the wind can blow through them, and finished in the sun. Put in a box and sweat for a month after drying. Treat peaches and nectarines the same as apricots. The quicker these are dried the better. Pears make excellent dried fruits and should be heavily sulphured (2lbs. sulphur to 60lbs. fruit for about 18 to 20 hours). They should be dried in the shade. Apples are not very successful to dry, and involve a good deal of trouble. Grapes make some of the finest dried fruit that can be obtained. They should be put in a caustic soda dip (1lb. to 10galls. of water) and dried in the sun. All fruits should be packed in a sweat box to finish off, so that all are equalised as regards moisture. As regards the fruit grub, if care is taken, the fruit not left lying about, and the boxes lined with grease-proof paper, no trouble should be experienced. After drying and sweating (apricots, pears, peaches, &c.) a dip of wattle gum prevents attacks of grubs. A glycerine and treacle dip can be used for all fruits. Mr. H. Parsons read a paper, "Lessons from 1930." (Secretary, Mr. A. Lowe, c/o Jacob & Russell, Pirie Street, Adelaide.)

#### RAPID BAY.

November 13th.—Present: 14 members.

**MAKING FARM LIFE ATTRACTIVE.**—Mr. R. Hooper read the following paper:—"It is essential to adopt a definite system of farm management. It is a good policy to allow the hired farm hands (or the sons, as the case may be) some interest in the farm. Cows are a skie line on most farms, and if the man looking after the cows is given a percentage of the cream cheque in addition to his wages, he will naturally endeavor to

obtain the best results. In the matter of the cows themselves, it pays a farmer to keep a good, well-bred herd. Purchase a good bull. Breeding your own stock becomes very interesting, and leads to taking a pride in the farm. If a farmer using horse teams cannot afford to purchase a stallion he should try to secure the services of a good type of stallion for his brood mares. The Clydesdale or Suffolk Punch breeds are good types for farm work. Care of the horses in a point of most importance. A good stable with a straw roof, being cool in summer and warm in winter, goes a long way towards keeping horses fit for work. Grooming is also an important factor in keeping horses fit. It takes time to give horses proper care and attention, but the only return they get for their work is their keep, so surely all fair-minded men, who are responsible for their care, should treat them well. In these times, when every item of expenditure calls for close scrutiny, it will pay farmers with horse teams to see that their harness sets receive the best care and preservative treatment to ensure that they last as long as possible. A point of first importance in harness treatment is systematic oiling and cleaning. Only animal or vegetable oils should be used. Neatsfoot oil, or half Neatsfoot and half tallow melted together and applied warm is suitable. Fish oil is also recommended. It is advisable to wipe sweat-marked harness thoroughly dry after a day's work. All machinery and implements should be kept clean and as up-to-date as possible, so that the work is easily and well done. During seeding and harvesting season a reliable man should be allowed to carry out his ploughing or drilling, reaping, or whatever he may be doing, in his own way, as if the farm was his own. He will be more interested and take a greater pride in his work if allowed this freedom."

A special meeting was held on November 26th. Mr. C. Goddard, of the School of Mines, delivered an address, "Sheep Management and Handling the Clip." (Secretary, Mr. L. Morris, Delamere.)

#### RAPID BAY.

February 12th.—Present: 11 members.

SOIL FERTILITY.—Mr. J. Muller read the following paper:—"The most common cause of infertility of soil is lack of humus, though there are quite a number of causes that have the effect of making soil infertile, such as lack of minerals that supply the plant food, or the soil may be in such a condition that plants cannot avail themselves of that food; or it may be too wet or too dry—each one of those causes would have the effect of plants not thriving. Yet the soil could only be classed as infertile. In most cases, the reason why soil is deficient in humus is that it has been depleted through constant cultivation, more especially where the wheat-fallow system has been adopted and no provision has been made to replenish the drain on the natural supply. If farmers would only study and adopt the laws of Nature, such a state of affairs would not be so marked as it is in some cases. Some soils also stand more abuse in that direction than others, but there is no excuse for abuse, more especially when it touches one's own pocket. The thing then is how to stop the depletion. There is no doubt that rotation of crops will go a long way towards solving that problem, because one kind of crop invariably leaves the soil in a better condition for another kind of crop. Unfortunately, in most districts the farmer has not a great variety of crops to choose from—at least, not what would turn out a profitable proposition, and that is, after all, the main governing factor. On the other hand, some districts, especially those with a good rainfall, have quite a number to choose from. Where peas do well, there is no crop to compare with it for keeping up the fertility of the soil, but the same thing applies to all the legumes, though perhaps not to such a great degree; but they all leave the soil in a good mechanical condition, and if that can be followed by a crop such as rape or swedes, that could be fed down with sheep, there is no doubt it would tend to increase, instead of diminish, the amount of humus. The gardener is in a more enviable position in that respect than the farmer, in that he has a greater variety of crops to choose from, but a lesson can be learned from that source. The method adopted by most gardeners is to follow a crop that grows above the ground by one that grows under the ground, such as root crops after potatoes and potatoes after peas or beans, &c. Lack of plant food is also a governing factor in infertility, or perhaps plant food in an unbalanced form or quantities. Unless the soil is waterlogged, it generally contains most of the minerals that are required; the exceptions are phosphates, nitrogen, potash, lime, and lately some soils have been found to be deficient in manganese. Every farmer knows that to grow crops phosphates are necessary, but there are quite a number that still ignore the other constituents which in some cases are just as necessary as phosphates. How often do we see a crop that has the yellow-green appearance that denotes the lack of nitrogen, but as nitrogen in the commercial form is often too expensive to use, the growing of a legume, such as peas or clover, is often quite possible. Rape also is a crop that can be grown in a number of instances and is highly recommended for fattening sheep, lambs, and pigs, the droppings of which, and the rotting of the roots, all help to increase the fertility of the soil. Rape is a member of the *Brassica* family, and thrives best where

nitrogen is more plentiful, so it is advisable to sow it after a crop of peas. It also has the advantage of cleaning the ground where peas have the tendency of making the ground dirty. Ploughing under green crops has a tendency to sour the soil, and requires sweetening afterwards, but it is very useful in replenishing the soil with humus. In the wetter districts of the State the soils are mostly more or less sour. This can be overcome by the application of a dressing of lime, but as lime is generally too expensive, fallowing or the growing of a leguminous crop is to be recommended where large areas are to be cultivated, though the difficulty can be overcome by the application of lime where the area is only small. In most of the Hills gardens sourness is never encountered, which is probably accounted for by the fact that most gardeners use large quantities of bone dust, which contains 40 per cent. water soluble phosphate, which is mostly lime. In our grass lands, maintaining soil fertility is a much simpler job, as we have the assistance of Nature more at our disposal than with our cultivated lands. All that is necessary is to top-dress the pastures with a manure or a mixture of manures suitable for the grasses or clovers, and in some cases to the soil and the climatic conditions. Conditions vary so much in different districts that it is advisable for every farmer to do a certain amount of experimenting, even if only in a small way." (Secretary, Mr. L. Morris, Delamere.)

#### SHOAL BAY.

November 4th.—Present: 11 members and four visitors.

Mr. Turner reported having logged down scrub on the site for the proposed pasture experiments. A report of the Annual Congress was given at the meeting held on October 7th. A formal meeting was held on December 2nd. (Secretary, Mr. H. Bell, Wisanger.)

BALHANNAH.—Mr. E. W. Mattner presided over an attendance of 19 members at the meeting held on February 27th. Mr. H. N. Wicks delivered an address, "The Home Flower Garden." The retiring Hon. Secretary (Mr. H. Spoehr) was presented with an E.P. cake dish in recognition of his services to the Branch. (Secretary, Mr. C. Grasby.)

# CROWN LANDS.

---

## LANDS TO BE OFFERED SHORTLY.

Lands in the Hundreds of BENARA, COMAUM, GAMBIER, JESSIE, JOANNA, KONGORONG, LAKE GEORGE, MAYURRA, McDONNELL, MOUNT BENSON, NARACORTE, RIVOLI BAY, STIRLING, SYMON, and WATERHOUSE.

When offered full particulars will be published in the *Government Gazette*, and plans and detail may be obtained on application to the Director of Lands, Adelaide.

---

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

---

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

---

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

# AGRICULTURAL PUBLICATIONS.

The following publications have been issued and are available for distribution at prices mentioned :—  
**"First Aid to the Horse,"** by F. E. Place, B.V.Sc., M.R.C.V.S., &c. ; price, 3s. ; posted, 3s. 2d.  
**Journal of the Department of Agriculture,** 5s. per annum in advance ; 1s. per single copy to residents in South Australia. Other places, 10s. per annum ; single copies, 2s. each.  
 The bulletins and leaflets may be obtained by sending a 1d. stamp for postage.  
 All communications must be addressed—Ed., "Journal of Agriculture," Box 901E, G.P.O., Adelaide.

**THE AGRICULTURAL BUREAU.**—Particulars of this Organization, of which every farmer should be a member, can be had on application to the Department.

# **CLOVER TROUBLES**

## **in PASTURES.**

Mr. R. Crowe, Export Superintendent of the Department of Agriculture, Victoria, emphasises the bad effect of excess clover on the keeping qualities of milk, cream, and butter in an article on "Butter Factory Management," extracts of which are published in the *Victorian Journal of Agriculture* for August, 1930. For those dairymen and lamb raisers who encounter bloat and kidney disease in stock and "clover taint" in milk it is essential to obtain more grass in proportion to clover in their pastures. Autumn is the best time to rectify the trouble, and the following system should prove satisfactory :

- 1.—Autumn Harrowing and Reseeding with Wimmera rye grass in low rainfall areas and perennial rye and cocksfoot under moister conditions.
- 2.—Application of Sulphate of Ammonia.  $1\frac{1}{2}$  cwt. per acre in April or May after soil has been well saturated by Autumn rains.
- 3.—July Application of Sulphate of Ammonia 1 to  $1\frac{1}{2}$  cwt. per acre. In addition to improving the grass-clover balance the use of sulphate of ammonia will provide valuable grass growth during the Winter and early Spring months.

## AGRICULTURAL VIEWS AND COMMENTS.

### MISCELLANEOUS.

#### Agricultural Bureau Conferences.

District Conferences of Branches of the Agricultural Bureau are being arranged as follows:—

Far West Coast, at Ceduna, July 1st (Mr. E. H. Fear, Secretary).

Upper North, at Willowie, July 15th (Mr. H. A. Crisp, Secretary).

The above Conferences will commence at 10.30 a.m. in each case. Papers and questions for Conferences should be sent to the General Secretary, Agricultural Bureau, about a fortnight prior to the respective dates mentioned.

#### World Production.

In a communication early this month the Secretary of the Department of Markets furnished us with the following particulars relating to the production of primary products:—

| Article.              | World Production (Latest Figures Obtainable). | Australian Production.                                      |
|-----------------------|-----------------------------------------------|-------------------------------------------------------------|
| Wool .....            | 3,748,310,000lbs.                             | 875,000,000lbs. (1930-31)                                   |
| Wheat .....           | 3,687,710,000bush.                            | 213,265,650bush. (1930-31)                                  |
| Flour .....           | Not available                                 | 1,130,760 tons (1929-30)                                    |
| Barley .....          | 1,392,986,000bush.                            | 7,588,852bush. (1929-30)                                    |
| Beans and Peas .....  | Not available                                 | 812,760bush. (1929-30)                                      |
| Maize .....           | 2,778,554,000bush.                            | 7,946,320bush. (1929-30)                                    |
| Oats .....            | 2,915,115,000bush.                            | 14,424,186bush. (1929-30)                                   |
| <i>Dried Fruits—</i>  |                                               |                                                             |
| Currants .....        | Not available                                 | 15,460 tons (1930-31)                                       |
| Sultanas .....        | Not available                                 | 25,334 tons (1930-31)                                       |
| Lexias .....          | Not available                                 | 5,200 tons (1930-31)                                        |
| <i>Canned Fruits—</i> |                                               |                                                             |
| Apricots .....        | Not available                                 | 183,076doz. 30-oz. tins                                     |

#### The Canning Industry and the English Market.

Referring to the opening of a new canning factory at Worcester, England, the Minister for Markets, when questioned recently, stated that while Great Britain had made rapid strides in the last five years in the development of local canning of fruits and vegetables, it was not anticipated that such development would materially affect Australian exports of canned fruits, although Tasmania may be slightly affected in regard to berry fruits. Australia's principal exports in canned fruits were peaches, pears, apricots, and, to a lesser degree, pineapples—fruits with which Great Britain was not able to compete. Great Britain's activities were principally directed to the canning of plums, cherries, and berry fruits such as strawberries, raspberries, loganberries, gooseberries, and black currants, and in the vegetable line principally peas, but also beans, asparagus, carrots, and new potatoes. For these products the English climate was particularly favorable. The excellent flavor for which English fruits are renowned was a great asset. The development of the local canning industry has undoubtedly filled a great want in securing for home-grown products continuity of supplies throughout the year and the prevention of seasonal gluts. In the pea-canning section of the industry marked success had been achieved, resulting in largely increased sowings. It has been

stated that the demand has been extraordinary, and that last year the pack was double that of 1929. Success had been achieved through the greater recognition, by the English public, of the excellence of the home-grown product and its distinctive appeal to the palate, the attention paid to high class quality and perfecting processes, and the increased facilities for scientific canning on a commercial scale. One development has been the use of the leading packers of the gold lacquered container, with the sales advantage of a pleasing bright gold interior reflecting the natural color of the contents. Another factor in the development of the industry has been the crusade carried out by the Empire Marketing Board and the Ministry of Agriculture, and the introduction of a national mark for English canned goods. Movements are, it is reported, now afoot to standardise sizes of containers, and all aspects of the industry are being tackled with thoroughness to ensure the retention of the Home market and open the way for extension of trade to foreign countries.

#### **Publications Received.**

The Library of the Department of Agriculture acknowledges the receipt of the following publications:—

Report of the Proceedings of the Imperial Wool Research Conference, 1930. Price 1s. net.

Report of the Federal Dairy Investigation Committee, Part I.—Farm Production.

### **AGRICULTURAL INQUIRIES.**

---

[Reply supplied by PROF. A. J. PERKINS, Director of Agriculture.]

---

#### **Mixing Super with Guano.**

*"Is it advisable to mix super and guano and sow them together at seeding time?"* ("W. A. S.," Lake Wangary.) Reply—The composition of guano is exceedingly varied, even in the same deposits, and therefore it is impossible to express an opinion on the value of the particular type of guano you propose using. In the circumstances, the practice I would recommend would be as follows:—

Drill the guano in before seeding, even as early as February or March, if found convenient, and drill in the wheat with the superphosphate as usual. The main reason for this practice would be that young wheat plants require to come almost immediately under the stimulating influence of readily soluble phosphoric acid, which they find in superphosphate. The phosphate present in guano is not water soluble, and therefore would not be so readily available to the young wheat plants. Guano super is guano treated with sulphuric acid in the same way as phosphatic rock is treated in the manufacture of superphosphate.

Some guanos contain appreciable quantities of nitrogen, which in certain circumstances may prove of advantage to the crop, although heavy quantities of nitrogen generally lead to rank late ripening crops which are very much likely to be blighted off in unfavorable seasons.

---

[Replies by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

---

#### **Feeding Off a Growing Crop.**

*"At what stage should sheep be first turned on the crop?"* (Blackheath Agricultural Bureau). Reply—The general experience of the cereal-growing districts of South Australia is that crops should not be fed-off by sheep unless they are making excessively luxuriant growth in the early stages. In those few districts in the State where the cereal crops grow so rankly that they lodge when only 6in. to 8in. in height, it is the

usual practice to feed the crop close to the ground, but in other cases harm is generally done by allowing livestock on to the crop. If sheep are to be put on the crop it should be done as soon as the plants lodge, provided the soil is not too wet at that time. The crop being grazed should be fed off as rapidly as possible, and the sheep be removed as soon as the land is bared. A relatively large number of sheep should always be used, otherwise the animals pick out the weaker patches and shorter growth, and leave the over-rank places which would benefit from being fed off. Except in the case of excessive rankness of the young crop when benefit follows grazing off, the grain yield of practically all crops is reduced by feeding them down. In most of our wheat-growing districts on no account should stock be allowed on cereal crops after mid-July.

#### **Strawberry Clover on Swamp Land.**

*"Would Strawberry Clover do well on a swamp near Mannum still in its natural state, and how can the clover be established?"* ("G. H. M.," Mannum.) Reply—The two essential requirements for strawberry clover to make full growth, are (1) plenty of organic matter in the soil, and (2) perpetual dampness or even wetness, to the extent of water a few inches in depth. If your swamp is similar to so many of the small swamps on that part of the River Murray, this clover should give very high returns of first-class fodder for dairy cows. The best way to establish the strawberry clover in wet locations is by rooted sections or by sods. If you seed down a small area in a plot which can be watered, plants or sods can be put out in the swamp. If possible to walk on the swamp, rooted sections of old plants, or seedlings, can be transplanted, but if unsafe to walk on the mud, small sods from 1in. to 2in. square can be cut from the seedbeds and be thrown into the mud. The seed can be sown any time in the year in seedbeds, but as many samples of seed are rather poor germinators, all seed should be treated before sowing. If a sheet of rather fine sandpaper is tacked on to a board, the seed can be scarified by spreading it in a thin layer on a table or floor and gently rubbing it with the sandpaper. Just enough pressure should be used to scratch the surface of the seeds without crushing them. Once the seeds have germinated, the plot should receive plenty of water, as this clover is a water-lover.

#### **Oats for Hay and Greenfeed.**

*"What is the best variety of oats to sow for hay in a Hills district with about 35ins. of rainfall, best time to sow the crop, and what is the best variety for greenfeed?"* ("J. R.," Longwood.) Reply—Of the oat varieties suitable for hay and usually obtainable in this State, the order of preference for your district would be Sunrise, Algerian, and Lachlan. Sunrise requires the use of a little more seed than the other sorts, and the seeding should consist of about 70lb. to 80lb. per acre; whereas for the other two kinds, about 60lb. to 70lb. should be sufficient. Oats require plenty of time to mature if the crop is to give full returns, so the seed should be sown early in autumn, when rains have been sufficiently heavy to bring about a germination of seed. In your district late April would be best seeding time, but good results should follow seeding during the month of May. Best results would probably be secured from Early Burt, Bathurst Early, or Lachlan. When seeding oats for greenfeed, plenty of seed should be used, say 80lb. to 100lb. per acre. In your district a greater cut of winter greenfeed would be secured if a mixture of 40lb. oats and 30lb. rye was sown instead of oats alone.

#### **Lucerne Flea.**

*"The lucerne flea is doing a good deal of damage in this district. Is it likely that lime can be successfully used as an insecticide for this pest?"* ("A. N. W.," Woodside.) Reply—Lucerne flea is much more prevalent than is usual at this time of the year, and has done considerable damage to leguminous crops in many parts of the State; till it will be surprising if it affects spring growth of Subterranean Clover to any great extent. We know of no case where lime in any form has been used successfully to

# Farm with the Fordson ... for increased profits

**F**arming, like any other business, produces profits only when the costs of production are less than the market price of the commodities produced. In difficult times, profits are made only by those who find the means of increasing efficiency and lowering costs. These are the men who today are using the New Fordson Tractor ... the men who have *proved* that substantial savings are made possible by the Fordson's low cost, low depreciation and low working expense.

With the New Fordson you can do the work of an eight-horse team ... faster, better, and much more economically. Every farming job is done on time, with no costly delays for feeding, harnessing or resting. And when field work is slack, you'll always find a job for the Fordson at haulage or belt work. It is the handiest power unit you can have on the farm, and is never idle plant.

Ask your nearest Ford Dealer for the full story of the New Fordson Tractor ..... Ford Motor Company of Australia Pty. Ltd.

*The Standard Fordson: £220 at nearest Ford Works. Sales Tax Extra.*

*With the New Fordson Tractor you can cultivate 25 acres per day (against an eight-horse team's 15 acres) on much less than half a gallon of power kerosene per acre.*

*The NEW* **FORDSON**  
**Tractor**

control this pest, but on the favorable results secured by the use of lime-sulphur, we would suggest that you try this material. Lime-sulphur is sold by all suppliers of gardeners' requisites, and the commercial solution should be mixed with 50galls. of water and sprayed on the short pasture at the rate of from 70galls. to 90galls. per acre. The liquid is non-poisonous, and livestock can be returned to the fields a few hours after doing the spraying. If you intend to try lime it should be in the form of slaked lime when applied, as most forms of agricultural lime will be ineffective as insecticides. It will probably take 3cwts. to 4cwts. of ordinary slaked lime to give the pasture a sufficient sprinkling to have a chance of destroying the insects, and such a dressing would be beneficial to the soil. The slaked lime can be applied at any time during the day, and as soon as the slaking has been completed, without injury to the plants. Lime would benefit the soils of the Woodside district for general cropping purposes, but is not necessary for Subterranean Clover, this particular crop only requiring liberal applications of phosphatic manures. If lime is to be applied to improve the soil, the application should be from 10cwts. to 1 ton of slaked lime per acre, broadcasted on the land after it has been ploughed and cultivated, and then be only harrowed into the surface soil.

#### Reverse Clover.

"Can the Department of Agriculture give any information concerning a clover known as Reverse Clover in Western Australia?" ("H. P. B.," Birdwood). Reply—This clover is known in Western Australia as Drooping-flowered Clover (*Trifolium cernuum*). A leaflet issued by the Western Australian Department of Agriculture says that Drooping-flowered Clover prefers moist or even wet soils, and will withstand inundation in the winter months, but in drier soils it is not as successful as Subterranean Clover. The clover is readily eaten by stock. Messrs. Goldsbrough, Mort & Co., Limited, Melbourne, advertise seed at 7s. 6d. per lb.

#### Linseed Growing.

Correspondents seeking information on the cultivation of linseed in South Australia have been advised by Mr. W. J. Spafford (Deputy Director of Agriculture) that although linseed has been tried at various times and in all of the better agricultural districts of the State, it has never proved sufficiently profitable for farmers to continue with the crop. As a matter of fact, no linseed whatever has been grown here since 1920.

*Soils Suitable.*—The crop requires very fertile soil, and in all probability such soils as the chocolate-colored ones of the Adelaide Hills and the drained lands and volcanic soils of the South-East would grow the crop well if other conditions were favorable.

*Rainfall Required.*—If the average annual rainfall is not somewhere about 30ins., irrigation will be required.

*Class of Manure Suitable.*—The manures required will depend on the rotation of crops being practised. Where the land is spelled from crops fairly frequently, 2cwts. of superphosphate per acre would be sufficient, but under fairly intense culture 1cwt. sulphate of ammonia per acre should also be used.

*General Cultivation, &c.*—The cultivation of the land must be very thorough, and particularly so as regards the control of weeds. Clean land is of the utmost importance, and difficulty is experienced in this connection, because the crop should be sown fairly early to give it sufficient time to mature properly. In a general way it may be said that the crop is grown in a similar manner to the cereals, using from 1bush. to 1½bush. of seed per acre. It has, however, a disadvantage not common to the cereal crops in that the boll-worm appears to be very partial to the seeds, and when present will ruin the crop.

*Can it be Grown Within One Mile of the Coast?*—The coastal influence does not appear to retard the growth of the crop.

*Approximate Yield per Acre?*—Varies between very wide limits in this State, from very low yields to as high as 20bush. per acre. This liability to vary so much seems to be one of the principal causes of the unpopularity of the crop.

*Yearly Output for South Australia*.—No linseed has been grown in South Australia since the year 1920.

*Yearly Importation from Overseas*.—We import from India about 5,000,000lb. of linseed annually, about 18,000galls. of linseed oil, and about 30,000lbs. of linseed cake. Much of the oil extracted in South Australia is exported to Western Australia.

## HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. GEO. QUINN, Chief Horticultural Instructor.]

### Black Apricots.

*"What is the cause of 'black' apricots found on the trays after the fruit has been sulphured?"* (Rameo Branch of the Agricultural Bureau.) Reply—As far as I am aware the subject of the appearance of "black" apricots on trays has never been closely investigated. It has been assumed that they are the product of fruits which, for some reason, have not developed to the normal stage of ripeness, though seemingly so when passing the preparatory stages of drying. It is well known that apricots in which the starch has not changed into sugar will not readily respond to the sulphuring process which fixes the color in normally ripened fruits. Again, apricots or other fruits in which over-ripeness induces a return to acidity may re-act in a similar manner.

### Lemon Tree—Shedding Fruits.

*"Will the Department explain the cause of and suggest treatment for a lemon tree, the fruit of which, after it reaches fair size, drops off?"* ("H. D. S.," Bowhill.) Reply—The dropping of the young lemon fruits is probably due to an irregular supply of moisture about the roots of the tree. Lack of nutrition is also a possible cause, and exposure to cold winds also may contribute. I suggest watering the tree systematically, and giving an occasional dressing of sulphate of ammonia, dissolved in with the irrigation—using not more than 1lb. per annum for each year of age of the tree, assuming it has grown well.

### Planting Hardshell Almonds.

*"What are the best hardshelled almonds and what is the best method of planting?"* (Springton Agricultural Bureau.) Reply—There are scarcely any named sorts (other than the true Jordan variety) of hardshell almonds grown here. The almond varieties have apparently been crossed so much that there is no certainty whatever that the progeny from sweet-kernelled nuts will produce almonds with sweet or bitter kernels or

hard, soft, or paper soft shells. Any kind of hardshelled almond would do for planting. The best plan when planting *in situ* is to prepare holes—20ft. apart on the square system—by breaking the land to a depth of, say, 18in. at least and planting three nuts, say, 6in. apart in triangular order about a stake. Put them 2in. under the surface in early winter, if possible, whilst the soil is still warm. If several trees grow, the surplus plants may be transplanted at the second winter to fill any gaps.

#### Citrus Growing in Southern Districts.

Mr. C. H. Beaumont (District Horticultural Instructor) has informed a correspondent that citrus trees are grown in the Southern District mainly in two localities—Langhorne's Creek and Inman Valley (with Hindmarsh River)—the first with light rainfall (15in.) and irrigated, the other with heavier rainfall (26in.) and not irrigated (with one exception). In the irrigated section the soil is most varied, being from sand to heavy black loam, and formed by the overflow of the Bremer River; the water supply for the trees depends on the overflow of this river, so that it is irregular. Trees generally do well, even though they have many set backs, especially through lack of water when most needed. In the non-irrigated area the soil also varies, being made up by the overflow of the Inman and the Hindmarsh, but is mostly from good sandy to heavy black loam. The irrigated section has no very serious diseases, black scale being the worst insect pest and collar rot and brown rot the worst fungus pests. Red scale has started in one or two plantations in the Inman district, otherwise pests are the same as at Langhorne's Creek. Insect pests are controlled mainly by white oil sprays or by fumigation with hydrocyanic acid gas, generated by wet or dry methods; fungus pests are controlled by pruning and by the use of Bordeaux mixture. The groves are usually ploughed in September or October and are kept clean through the summer by cultivation, but in winter, either a cover crop of peas is grown or weeds allowed to grow, to be finally ploughed in as green manure. Trees are fertilised with sulphate of ammonia, 2lbs. to 4lbs. per tree at time of ploughing, but if peas are used then 2cwt. of 45 per cent. super per acre are sown with them. Any pruning is carried out about May and June, and consists mainly of removing excess twigs and dead wood, and keeping limbs up from the ground, the idea being to have the tree fairly open and of good shape. Picking of fruit commences in the irrigated section about July-August and finishes about November, and in the non-irrigated area starts about October and ends in December-January. The fruit generally is sweet and juicy and of good size, but at times is thick skinned; it is sized and packed by the owner growers for the local and city markets. The orange mainly grown is the Washington Navel, though there are a number of seeded varieties still grown, and Valencia Late is on trial. Lemons are not grown extensively, and the Lisbon is the most favored. Hailstorms are a trouble, and at times the skin of the fruit is severely damaged, but on the whole climatic conditions are good, and are suitable for the production of good fruit. Holdings vary from 50 to 10,000 trees, and the trees bear well.

#### VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

"A. S. D.," Kilkerran, reports two horses lame in front legs. Swollen above hoof and discharging matter. A split has appeared across the front of the hoof. Reply—The following treatment is advised:—Search out sole carefully below where the breaking-out first took place. The condition points to a puncture in that part. If present, open up, foment daily, dress with pure lysol and keep clean. In any case foment foot for two or three days, then open out the fissure or crack and dress with strong tincture of iodine. Subsequently cover with the following dressing:—Lard, 1 part; turpentine oil, 1 part; beeswax, 1 part. Further, rub the following blister into coronet above crack every third day or so:—Cantharides blister (1 in 24 of lard), to be obtained from chemist.

"*L. T. M.,*" Delamere, reports heifer on first calf going dry over night. Milk thick and discolored. Slight falling off in condition. Reply—The heifer probably has a subacute mammitis (inflammation of the udder). Give a drench of 1lb. of Epsom salts, and subsequently give 1 teaspoonful of powdered nux vomica (mixed with treacle and smeared on the tongue) night and morning for 10 days. Three times daily massage the udder for 10 to 15 minutes with warm camphorated oil, and if one quarter is weaker than the others, strip it out five to six times during the day.

"*H. W. C.,*" Stansbury, asks if syringing a cow with Condy's would have the effect of not being able to again get her in calf. Reply—No, provided it was not done within a day or two before the service. The cow has probably a chronic metritis.

"*Mrs. M. A. C.,*" Parrakie, reports cow with eruption on udder. Teats and udder are blistering and of a dark-purple color. Reply—After each milking bathe the skin of udder and teats with warm water to which has been added a little lysol. Dry gently after this bathing, and then smear over lightly with some 5 per cent. carbolic vaseline or zinc ointment. If healing is tardy, a few drops of Friar's Balsam may be incorporated into the ointment used. It would also be advisable at the commencement of treatment to give the cow a purgative dose of medicine—*e.g.*, Epsom salts, 1lb.; molasses, ½lb. to 1lb.; ground ginger, 2ozs.; warm water, 1 quart. Mix these all together and give as a drench.

"*E. H. C.,*" Meribah, reports young sows, after having had a litter, lose use of hindquarters. Reply—The condition in your sows is a *post-partum* paralysis. Young sows used for breeding purposes should not be too fat, and should have plenty of exercise. Green feed, and especially lucerne, during the summer should be supplied to them when possible. When the young sows have farrowed, give linseed meal (10 per cent. of the ration) where skim milk is not available. In the case of young sows, the litter may be too large for the sow. Further, have the following mineral mixture made up:—Wood ashes, 1 part; coarse salt, 1 part; sterilised sweet ground bonemeal, 2 parts. Give 4 tablespoonfuls of this mixture in the feed daily to a sow with litter. A sow and litter should have plenty of exercise, dry quarters, and as much change of feed as possible. Wheat should not be boiled. It is preferable to soak it.

"*Mrs. M. A. C.,*" Parrakie, reports young pig stiff in front legs and walks on its knees. Reply—The pig is apparently suffering from a condition very much similar to rickets. It is doubtful if any treatment will produce very satisfactory results, but the following may be tried:—If possible, provide a liberal allowance of skim milk in the diet or else give about 5 per cent. linseed meal in the ration. Give 1 to 2 tablespoonfuls of bicarbonate of soda (baking soda) in the trough feed daily, and 1oz. Epsom salts once weekly; 2 teaspoonfuls of cod liver oil should also be given daily.

## POULTRY INQUIRIES.

[Reply supplied by Mr. C. F. ANDERSON, Government Poultry Expert.]

### Poultry for the Redhill District.

*"What is the best breed of fowl for this district?"* (Redhill Agricultural Bureau.)  
Reply—The answer to this question depends on two circumstances—(1) Whether the fowl is required solely as an egg producer; or (2) whether a bird is required that will lay a fair number of eggs, and at the same time provide a good table bird. If the birds are required for egg production only, then the outstanding breed is the White Leghorn. The Australian White Leghorn, and South Australian in particular, is outstanding as an egg producer. In flocks of 200 birds or over, they are easily two to three dozen eggs a year ahead of any other breed. The fertility is better, the hatching is better, and they are more easily handled, and they will stand hot temperatures better than any other bird. If a dual purpose is required, then one of the heavier breeds is necessary and I recommend either the Black Orpington, Rhode Island Red, or Light Sussex. The Black Orpington has been specialised to a larger extent during recent years as an egg producer than any of the heavier breeds. However, there are also several good laying strains of Rhode Island Reds and Light Sussex. In any case, whatever breed is selected, special care should be exercised to see that the particular strain selected is a producer of 20z. eggs or over, as with the industry it is of the utmost importance that as large a percentage of 20z. eggs and over as possible be produced, in order that a profitable export trade be built up.

## DAIRYING INQUIRIES.

[Reply supplied by Mr. H. B. BARLOW, Chief Dairy Instructor.]

### Pigs for Eyre Peninsula.

*"Can the Dairy Branch of the Department give information concerning the advisability of making a cross of the Large White and Middle White pigs, and some idea as to the best weights at which to sell the pigs?"* ("C. B." Yantanaby.) Reply—The dead weight for a bacon pig on the local markets is about 120-130lbs., dressed weight, or about 170-180lbs. live weight. The ideal pig of this weight should not be too fat, but evenly covered with about lin. of fat along the back. If the pig is too plump, although of the right weight, it would be termed over-fat. On the other hand, a pig might be too old, have grown in frame and bone, and although about the correct live weight, might be too lean or unfinished. I would suggest marketing pigs at never more than 130lbs. dressed weight, and the nearer to 120lbs., if well finished off, the better. With regard to your suggestion to go in for Large White x Middle White, I would suggest a little more consideration. This cross is accepted at the present time as the ideal export pig, but with your hot climate and distance from the port of shipment (Port Adelaide), it is questionable whether it would be quite sound at the present moment. I would suggest that you concentrate more on the local market, either Adelaide or Port Lincoln, at present, and with this object in view would suggest a pure Berkshire boar and Tamworth sows, or, if Tamworth sows are hard to procure, use a Berkshire boar on Berkshire x Tamworth sows. This cross is very acceptable for the local bacon trade, and the Tamworth sows are good mothers and have large litters. I think this suggestion is worth considering for the present, for even if a sound export market is opened, it would take you very little time to change over to the White pigs. Your remark about not being able to follow the local pig market suggests that the pig breeder's maxim is correct—"If you are going to breed pigs, keep on breeding, sell when in the right condition, and do not try and pick the market." If you have a regular supply you will catch the "ups" as well as the "downs" of the market.

## SECOND ANNUAL CONFERENCE OF S.A. BUTTER AND CHEESE FACTORY MANAGERS' AND SECRETARIES' ASSOCIATION.

OPENING ADDRESS OF THE MINISTER OF AGRICULTURE (HON. S. R. WHITFORD, M.L.C.).

It is with pleasure that I meet you again on the occasion of your Annual Conference and I take this opportunity, Mr. President, to congratulate you on your election as second President of the association. I feel that the association is fortunate in having at the helm in its opening years a man whose tact and high technical and business attainments are well calculated to steer it along the course of success.

I want, too, to congratulate you all upon the common sense that has led to the formation of this association; although I must add that, in these bustling times, it appears, if anything, to have been a shade overdue. Incidentally, of course, you are trade rivals, and as such engaged in trade warfare, not indeed on your own behalf, but on behalf of those whose special interests you happen to represent; but, on the other hand—and this, I take it, is your more important function—it is your business and privilege to convert into merchantable articles the primary produce that comes to you from our fields. In the latter connection, independently of any trade rivalry, you owe it to your clients, to your reputations, and to the State, to see that as far as in you lies, articles only of the highest quality that the raw material admits of should be allowed to leave your factories. And towards this end your mutual deliberations, coupled with such advice as the officers of the Department of Agriculture are always anxious to give, should eventually lead. The State has a very special interest in this aspect of the question; second and third rate articles, although regrettable, may sometime pass muster at home; but, as you are no doubt aware, our economic existence as a community is wholly dependent upon our ability to export commodities abroad at a profit; unfortunately, the number of these commodities is extremely limited; butter can, however, be reckoned among them, and probably cheese, too. And I need not remind you in this connection, that on the markets of the world "good enough" will not lead us anywhere: and that those responsible for the output of inferior articles not only injure themselves and their clients, but in addition hinder first class articles from realising their full value on the markets of the world, and do untold injury to the State, that stands in need of every penny that can be wrung out of overseas markets.

I know that I have laid myself open to the obvious retort that our overseas exports of butter and cheese are infinitesimal, and that over portion of each year we are actually obliged to import from neighboring States the butter we require for home consumption. I regretfully admit that such is undoubtedly the case—at present; but need it necessarily continue to be so indefinitely? Do not our interests as a State require that the dairying industry should expand and that dairy exports should ultimately throw into the shade the requirements of home consumption? And do not our local economic, climatic, and soil conditions permit of it, and in present circumstances even demand it? It is true that it has become customary to depreciate the value of South Australia's natural dairying conditions relatively to those of more generously endowed States, such as New South Wales and Victoria; we are said to lack that special type of permanent natural pasture that is so typical of normal dairy development. But what Nature has denied, art can frequently make good; the improvement of pastures by top-dressing and the introduction of suitable pasture plants has done much within recent years towards overcoming our natural disabilities; and it is safe to say to-day that every district with a yearly rainfall of not less than 20in. is a potential dairy district. Under this description would come our Northern and

Southern Hills Districts, the whole of the South-East, the Southern District, parts of the Lower North and of Yorke Peninsula, Southern Eyre Peninsula, and Kangaroo Island; whilst on the reclaimed Murray swamps we have probably the most productive dairy district in the whole of the Commonwealth.

But, in addition to this, dairying can be practised to advantage even under conditions that are well below the ideal. Of this we had striking examples in the dry nineties, when our northern farmers, after the failure of their crops, were actually kept on the land by their cows; later on more favorable seasons and high-priced wool made them forget their benefactors and discard cows for less exacting sheep; but to-day there is many a one who ardently wishes his cows were back at the pail again. And the dilemma of the northern farmer is being repeated on practically every wheat farm of the State; the decline in the price of wheat has been so pronounced that all are crying out for cows to provide their owners with ready cash to meet current expenses. There appears to me to be no reason why every farmer in the State should not, in the course of time, average six to 12 milch cows; and when this has been brought about, and suitable areas in the better rainfall districts have been split up into useful size dairy farms, our exports of dairy products should, under good management, exceed in quantity and value those of corresponding products consumed at home, much to the advantage of the financial standing of the State.

Such, then, is the goal that we should keep constantly before us; and our present necessities are so great that we should strive to reach it at the earliest possible moment. From the latter point of view, however, recent dairy statistics make most depressing reading. In 1923-24 we had 169,000 milch cows; in the same season we made about 7,700 tons of butter and 1,650 tons of cheese, whilst the estimated value of total dairy production in South Australia was approximately two and a half million sterling. Six seasons later, in 1929-30, our milch cows had fallen to 104,000, a decline of over 38 per cent.; our butter production to 4,800 tons, a decline of over 37 per cent.; our cheese production to 1,580 tons, a decline of close on 4 per cent.; and the value of total dairy production to less than two million sterling, a decline of close on 22 per cent. It is very clear, therefore, that there is very much leeway to make up before we can hope to benefit much from the advantages which dairying can confer upon both individuals and the State. Nor can we hope to come within reach of them in reasonable time, unless we can enlist the services of all men of good will, able to assist in however modest degree; and this is the chief reason why I am bringing the matter before you to-day.

For the most part you are stationed in country centres; your avocations bring you in daily contact with farmers and producers generally; your ability to give advice on a variety of technical questions tends to invest you with special influence in your respective districts. Is it too much to ask of you, as citizens of the State, to use that influence not only in the interests of the factories with which you may be connected, but also in assisting in the development and expansion of the dairying industry of the State?

I am not an expert on the subject, and have no intention of dictating what should be your course of action, and my suggestions on the matter must be taken for what they are worth.

I suggest that you should never weary of preaching the gospel of dairying to all likely to benefit therefrom; to the average farmer the advantages in these times of the fortnightly dairy cheque should be emphasised; to the regular dairyman the advantages of heavy milkers, of generous feeding, kindly treatment, high class bulls; and to all alike the absolute essentialness of the strictest cleanliness in all dairy work. I suggest that you plead for the heifer calf and stress the folly and lack of public spirit of disposing of it as a vealer, however tempting current prices might be. And in cases of special difficulties do not hesitate to call to your assistance officers of the Department of Agriculture.

May I suggest, too, that every one of you should be an active member of a local Branch of the Agricultural Bureau. In the latter capacity you should endeavor to overcome the unfortunate aversion of some farmers to the Dairy Industry Act; you should try and convince them that the sole object of the Act is to raise the standard of our dairy products to the possible maximum; that high quality of dairy products means improved average prices, reflected eventually in higher prices for milk and cream.

This is the merest sketch of what I imagine you can do for the public good; and I feel sure that I shall not have appealed to you in vain.

There is one other question upon which I would like to dwell very briefly; a question which, I understand, is giving grave concern to all those interested in the dairy industry—I refer to the threat of margarine to the industry. I think that I have made clear my opinion as to the great importance of the dairy industry to this State, and particularly in relation to the present financial crisis. I know, too, that at current prices for dairy products many dairymen find it difficult to make both ends meet; in the circumstances, with all those interested, I view with grave concern the appearance on our markets of an artificial product sold in open competition with butter. However much we may try to gloss over the fact, with statements to the effect that margarine cannot possibly displace first-grade butter on the home market, the fact remains that its presence on the market can have but one ultimate effect, and that is a general all round decline in butter prices, which will be calamitous to producers throughout the Commonwealth. I am informed that at the present time margarine is selling in Victoria at the rate of 30 tons a week, representing an output of approximately 1,600 tons per annum, with practically unlimited possibilities of expansion. The dairy interests of the other States are even greater than our own, and, personally, I am of the opinion that it would be a statesmanlike action to prohibit the manufacture of margarine within the Commonwealth and its importation from abroad. It is probable, however, that the beef interests of the Eastern States are too powerful to permit of any such action. I propose, therefore, in the interests of our own dairy industry, giving close consideration to a resolution passed at the 1927 Conference of Ministers of Agriculture to the effect that the use of milk products in the manufacture of margarine should be prohibited by law. It would appear that margarine cannot masquerade as butter, except with the assistance of skim milk, butter, &c., and it seems anomalous that an industry of so much importance to the State should be compelled to supply the weapons by means of which it will gradually be bled to death.

In conclusion let me express the hope that your deliberations will prove successful and help to improve general conditions in the dairy industry.

## THE PRODUCTION OF FAT LAMBS.

[By R. C. SCOTT, Supervisor of Experimental Work.]

At the present time the overseas market demands a small lamb dressing in the vicinity of 32lbs. to 36lbs., and for a carcass of this type is prepared to pay a higher value per pound, even if the quality is not as good as that of heavier weights. In order to take our place in the export trade, we must endeavor to produce a light-weight lamb with short, well rounded body, full loin, well covered withers, legs filled both inside and outside, and with the fat well distributed throughout the body.

As a rule, the breeder of fat lambs in South Australia is working under vastly different climatic conditions to those obtaining in the great meat exporting countries of the world, and must, therefore, adjust his plans to meet these special conditions. Our aim must naturally be to produce the most profitable type of lamb according to the climate, the system of farming in vogue, and the class of parents available. Lamb breeding cannot be commenced until the holdings have been prepared for stocking. On many farms this provision has been made, and where farmers are not already producers of fat lambs, the acquiring of a flock and commencement of operations is strongly urged. It is a system of sheep management well suited to our agricultural holdings, inasmuch as the flock is reduced to a minimum at the time of the year when pasture is scarce, and at its maximum when grass is abundant. It fits in well with the operations of a wheatgrowing farm, and is a source of revenue which should be adopted by every farmer as soon as conditions permit.

### CHOICE OF EWE.

As a mother for fat lambs, the crossbred ewe presents advantages over the Merino, and, as our export trade becomes established, so will the Merino be steadily replaced by ewes of this class. However, at the present time it is impossible to purchase any number of half-bred longwool ewes, whereas the Merino can generally be secured in an even line of any size and at any time of the year. It is a breed admirably suited to the climatic conditions of most districts, is easy to fence, and cuts a more valuable fleece than any other breed of sheep. For these reasons the farmer's lamb breeding flock must, for the present, consist usually of large-framed, plain-bodied Merino ewes. Independently of their availability, the half-bred longwool Merino ewe is the best mother of fat lambs, and in our higher rainfall areas is preferable to the Merino, and in the southern and south-eastern districts may be recommended to farmers. She offers the advantage of a higher lambing percentage, better-shaped and earlier-maturing progeny, and is able to withstand wetter and colder conditions better than the Merino. Either the Border Leicester, Romney Marsh, English Leicester, or Lincoln-Merino ewes may be utilised. Roseworthy College experiments indicate that, under the climatic conditions of that district, the Border Leicester-Merino is to be preferred, but in New Zealand the Romney Marsh-Merino mother is favored. If available in sufficient numbers and of uniform type, the Corriedale would prove a satisfactory mother for a lamb-raising flock. However, generally speaking, we have little option regarding the choice of a mother, since the half-bred longwools or Corriedales are extremely difficult to obtain. The Merino ewe must remain the farmers' sheep for the majority of our agricultural holdings, whilst in our higher rainfall areas the half-bred longwool should be secured when available.

Merino ewes of the type suitable for use as mothers of export lambs.

Half-bred long-wool ewes which can be regarded as the ideal mothers for export lambs.

## CHOICE OF SIRE.

The influence of a ram is to stamp special qualities on the progeny, and thus provide the type of lamb required for maximum returns. It is evident that the Merino is not suitable. Of the Longwool breeds, all are more or less defective, with the English Leicester the best of those available. This breed gives a fairly shapely lamb, and if the average climatic conditions of the district are such that there is a possibility of having to carry over a percentage of lambs until the following year, the value of the fleece or pelt is an important consideration, favoring the use of the English Leicester under such circumstances.

Regarding the Short-wool breeds, the Dorset Horn is a sire which imparts early maturity to his progeny. Lambs by this ram are well suited to the local market, and, owing to their rapid development, frequently command high prices early in the season

Southdown Ram.

when sucker lambs are scarce. However, for export purposes, they are not so satisfactory, as they tend to become too heavy before priming. In consequence, a large percentage does not answer the requirements for a light weight lamb, and, therefore, realise lower poundage values.

Of the Down breeds, the Southdown stands alone as a sire of lambs of the ideal type for the export trade. London buyers demand a relatively small, but well furnished, lamb, and the Southdown supplies these requirements better than any other breed.

The Shropshire ram yields a good class lamb, but there is always a percentage of a coarser type. On account of this irregularity, it is not equal to the Southdown for producing export carcasses, and its tendency to yield wool-blind lambs is also a disadvantage.

The Suffolk sires lambs almost as early maturing as those by Dorset Horn. The meat is of good quality, but, on the average, the carcass is not shapely, being long and lacking in depth and width.

Summarising the position from the point of view of the ram, the Southdown must be given pride of place for the production of choice, light-weight lambs.

If South Australia is to establish a high reputation in the overseas lamb market, we must ship a uniform type of carcass. The Southdown is the breed best able to yield lambs of the right quality, and as the sire for export lambs is to be strongly recommended over all other breeds.

The Suffolk and Dorset Horn have value in certain areas because of their early maturity, and occupy a definite place in the production of lambs suited to the local market.

## GENERAL MANAGEMENT OF LAMB-BREEDING FLOCK.

### LAMBING SEASON.

The main point is to so arrange the mating that the lambs are dropped at a time of the year when feed is plentiful. As soon as a young lamb requires more than its mother's milk, it must have good, succulent pasture, or else it gets stunted in growth. Therefore, the lambing time selected must be such that there is prospect of four to five months of good grazing ahead.

In cold countries, spring lambing is generally practised, but in South Australia lambing is chiefly confined to the autumn, when there is less danger from exposure.

Lambs from Merino ewes do not do well when dropped in cold weather, and for that reason, provided the feed conditions are likely to prove favorable, should be dropped towards the end of autumn or early winter. At this time the weather is milder and the lambs become strong before being subjected to cold, bleak conditions.

The average gestation period for a Merino ewe is 150 days, and therefore it will be necessary to mate up about five months before the time desired for the first lambs to be dropped. In most districts the lambing season extends from about mid-April to mid-June, in which case the rams would be joined with the ewes towards the middle of November.

### MATING.

When mating for fat lambs, the number of rams should not be limited, and, if possible, more than one should be turned in with the ewes, as they then work better than if alone. In ordinary circumstances, not more than 50 ewes should be mated to one ram, and preferably 40 for rams of British breeds.

The rams selected should be strong and healthy. If either too fat or too low in condition, the result is not likely to prove satisfactory. Ram lambs from six to seven months old are quite effective as sires, but it is not wise to use them as it checks their development. If the breeder has no alternative, he should mate the young rams with half the usual number of ewes. As a ram gets older he usually becomes slower to work, and should not be relied upon after he reaches full mouth. Shearing and dipping checks the desire to mate, and therefore these operations should be carried out at least a fortnight before joining with the ewes.

At times, particularly in warm weather or when the rams are carrying too much condition, it is difficult to get them to remain with the flock. In this case, it is advisable to yard overnight for a few times, and thus encourage mating. The rams may be allowed to remain with the ewes for from 8 to 10 weeks, and, if available, a fresh ram should be added during the last fortnight to help catch up any ewes that have been missed. The ewe should not be too old, and should never be broken mouthed. On the other hand, when young Merino ewes are mated to British rams, lambing fatalities are more frequent. The aim should be to secure 6-tooth to sound mouthed ewes, and cull as soon as there are signs of the teeth failing. Ewes should go to the ram in good store condition and be maintained in this state during the whole of the gestation period.

#### CARE OF LAMBING FLOCK.

If feed gets short in the autumn, the flock must be hand fed. It is a mistake to delay hand feeding until the paddock grazing gets scanty and the ewes become weak. With roughage in the field, a sheep can be kept in good health at comparatively little cost, and the expense is amply repaid. One pound of grain daily with 2lbs. to 3lbs. of chaff will be sufficient for the purpose.

As lambing approaches, the more sheltered fields should be reserved for the lambing flock. In most districts foxes prove troublesome, and for some time before the first lambs appear poisoned baits should be distributed. A satisfactory bait can be made by rolling a pellet of raw mutton containing strychnine, equivalent to the quantity

**Typical Export Lamb.**

which could be placed on a threepenny piece. The lamb is the source of revenue, and close attention must be given to the flock. During the lambing period it should be visited at least once daily and assistance rendered where necessary.

On the completion of lambing the dry ewes should be removed and placed on the poorer pastures, and the wet ewes and lambs on the most succulent feed available.

#### TAILING.

Tailing and castrating should be done when the lambs are about two to three weeks old. At this age they suffer less shock and recover more quickly than when either younger or older. Further, it checks the tendency towards coarseness and staggyneess of wether lambs. It is advisable to go through the flock two or three times during the lambing period, marking all lambs of about the right age. If an attempt is made

to do them all at the one operation some would be much too old. In order to avoid loss from tetanus, marking should be performed in a temporary enclosure erected in a well-grassed field.

#### MARKETING LAMBS.

The lambs should not be weaned before disposal, but marketed straight off the mother. It is essential that they carry what is termed "bloom," by which is meant the freshness and sappiness of lambs reared by good mothers in succulent pastures and marketed at the correct age. Most important in the marketing of lambs is the feed available. Nothing is equal to rich pasture, and hand feeding can never replace

First quality export lamb carcasses.

grass so far as the lambs are concerned. In abundant pastures, and with good milking mothers, a lamb will increase in weight at the rate of about  $\frac{1}{2}$  lb. per day from birth to the age of five months. When 14 to 16 weeks old, some lambs will be sufficiently prime and weighty for marketing. As has been said, the English market demands a lamb dressing approximately 32lbs. to 36lbs., and a lamb weighing from 70lbs. to 75lbs. on the farm will provide a carcass of this weight. A lamb weighed on the farm usually has a full belly, with the result that the shrinkage on dressing under such circumstances will vary from 52 to 57 per cent. On the other hand, lambs taken from their mothers for some time before slaughter, as is the case when consigned to the Depot, will lose from 48 to 54 per cent. of their pre-slaughter weight. Therefore, lambs should be consigned from the farm when in prime condition and from 70lbs. to 75lbs.

live weight. It is a mistake to keep them until they become too heavy, as when the feed is less succulent they tend to lose their "bloom" and thus command lower values, whilst grass seeds frequently penetrate the flesh and render the carcass unfit for shipment overseas.

Every care must be exercised to avoid bruising, as this is a cause of rejection for export which is far too frequent in our fat lamb industry. A lamb is very easily damaged, and the use of sticks, lifting by the wool, or rough handling in any way must be strongly checked.

#### SUMMARY.

1. The English market demands a light weight, prime quality lamb, weighing about 32lbs. to 36lbs.
2. On account of her availability and high valued fleece, the large-framed, plain-bodied Merino ewe must be utilised on the majority of agricultural holdings.
3. In higher rainfall and colder districts, the half-bred longwool Merino ewe offers advantages over the Merino.
4. The Southdown ram is the best sire for the production of lambs of the ideal type for export, but, if not available, Suffolks or Shropshires are permissible.
5. Lambs should be dropped at a time of the year when mild weather may be expected and there is prospect of several months of good grazing ahead.
6. Over the bulk of South Australia lambs should be dropped in autumn.
7. Not less than 2 per cent. of rams should be joined with ewes.
8. Use rams in good, strong condition, and not too old.
9. Mate only sound mouthed ewes in good store condition.
10. Allow rams to remain with flock for from eight to 10 weeks.
11. Adopt hand feeding in autumn as soon as pasture becomes short.
12. Give close attention to lambing flock.
13. Mark lambs when about three weeks of age.
14. Avoid loss of "bloom" by disposing of lambs when young.
15. Market lambs when 70lbs. to 75lbs. live weight on the farm.
16. Exercise care in handling to avoid rejection for export on account of bruises.
17. Maintain flock on most succulent feed available.

#### BLUESTONE FOR WORMS IN SHEEP.

"When dosing sheep with copper sulphate, with or without mustard, will there be any danger if the strength of solution is made three times as great as the quantities advised (½oz. to 3ozs.)?" Replying to this question, Mr. A. H. Robin, B.V.Sc., Government Veterinary Officer, says the Stock Department is now recommending the use of bluestone solution mixed at "double strength" to that formerly used (although, if weak sheep are to be treated, we consider it would be wisest to stick to the old strength, viz., 1 per cent.

The new proportions are therefore:—

- (a) Bluestone, 4ozs.; water, 1½galls.; or
- (b) Bluestone, 4ozs.; mustard, 4ozs.; water, 1½galls.

*Doses*:—Adult sheep (4-tooth and over), 2ozs.; sheep (12 months), 1oz.-1½ozs.; lambs (according to age), ½oz.-1oz.

The use of these more concentrated solutions means that the dose to be given per animal can be considerably reduced, which is undoubtedly quite an advantage. These solutions are well tolerated, and appear to be giving even better results in the field than the weaker 1 per cent. solution formerly recommended.

The administration of solutions stronger than the above concentration is not advised.

## THE POULTRY INDUSTRY.

*Address in connection with Presentation of Trophies Won in the Red Comb 1930-31  
Egg-laying Competition, held at Parafield Poultry Station.*

[By ARTHUR J. PERKINS, Director of Agriculture.]

Although this series of Competitions are open to any Poultry-Keeper in the State, the credit of initiating them belongs rightly to the Red Comb Association. There is sometimes a tendency to look upon Competitions of this kind as a means of advertising the birds of the lucky winners; personally, however, we may, I think, take a broader-minded view of their essential functions. They may be taken to represent a genuine effort to secure improved production in an important line of rural activity. The 185 birds under test in 1930-31 averaged 203 eggs for the 12 months (say 17 dozen); probably the mean yield of our average local hens would not be more than seven dozen over the same period of time. If the inherited tendencies of these heavy-laying strains were gradually spread over the State, and succeeded in raising the mean State laying production by a couple of dozen per hen only, this would represent increased production at the rate of £150,000 per annum for one and a half million fowls, which we possess at present, and this without additional handling or feeding costs. From this point of view I trust that the progeny of these Competition Fowls, like the leaven in bread, will gradually spread throughout the State and lead, in the course of time, to higher and more profitable egg-production.

From the latest available Statistics (1928-29) I find that the value placed on all South Australian Industries is approximately 36 million sterling per annum, and that in this total are included three items, the value of each of which is slightly over one million sterling, namely, Poultry, Mining and Quarries, and Forestry, &c. It follows, therefore, that Poultry Keeping ranks to-day with the great industries upon which State and Commonwealth depend for their economic wellbeing.

You must all be aware of the economic difficulties that are besetting us at the present time, and that in the main they are attributable, apart from past extravagance, to a calamitous fall in the prices of rural produce, by means of which we usually seek to meet our heavy commitments abroad. This means that, for the time being, we must strain every nerve to export rural produce—the only commodity that we are able to export in present circumstances—in far greater bulk, if not of greater value, than we have hitherto done. Hence, the great national importance that attaches to any rural industry that has a ready export outlet, and among these I am happy to think that the Poultry Industry can be included.

**EXPERT ADVICE ON GRASSES AND CLOVERS.**

I am, of course, aware that those who aim at exports must perforce face the ups and downs of fluctuating world prices, and that if everything be taken into consideration, individual losses are perhaps as frequent as net profits. For the past 12 months we have been compelled to watch our main export staple—Wheat—being exported overseas at a heavy loss to producers. We hope, indeed we know, that this is no more than a passing phase in our economic life, which all must face who are dependent upon the vagaries of World markets. Farmers know that the present position has been paralleled in our past history on several occasions, and in spite of their precarious position those with sufficient experience have not lost heart.

The point I wish to make is that Poultry-Keepers, like Wheat growers, cater not only for local consumption, but have also an export outlet to watch. I am told by Mr. C. F. Anderson (Poultry Expert) that here in South Australia we produce 70 per cent. more eggs than we can consume, and it follows, particularly if the Industry is to extend still further, that special attention must be given to the export outlet. And when the time comes, as come it must from period to period, that export prices are not altogether to our liking, and even may be below costs of production, it is to be hoped that Poultry-Keepers will follow the example of our hard-trying Wheat growers, and not scuttle for shelter and abandon an export market which it would take many years and much Capital to recapture.

Now, I think that it must be admitted that within recent times, with grain and mill offal at bedrock prices, Poultry-Keepers may be said to have been on a very good wicket. But let me say that, however great our temporary prosperity, this is hardly the time for motor cars and other luxuries, but the time to husband our resources so that we may be in a better position to weather the difficulties that are always in the offing.

I am, of course, aware that as soon as a surplus is in sight our thoughts turn to the populous centres of the larger States, and that in the past Broken Hill, Sydney, Melbourne, and Kalgoorlie have in order of importance absorbed portion of our surplus. And as members of a federation that has perhaps unconsciously built up secondary industries without possible export outlet at the expense of primary production, it is only right that we should have free access to the large cities that have developed as the immediate result of this policy. It is nevertheless necessary that some degree of common sense should be exercised in such matters. If any large city is short of eggs, and we possess a large surplus, it is sound common sense and of material benefit to all concerned that we should fill in the gaps from our abundance, but if that city is already adequately supplied from the immediate neighborhood, the result of such an invasion of the market can only be an all round fall in prices, with the probable consequence that city folk are supplied with rural produce below costs of production. This indeed is the usual historic tribute which the country has paid to dense centres of population. As a matter of fact, I am informed that, in the aggregate, New South Wales, Victoria, and Queensland have already a 25 per cent. surplus of egg production. Is it not well, therefore, that we should come to an understanding before attempting to fight them on their own markets? Our geographical position appears to suggest that we can meet the requirements of Broken Hill and Kalgoorlie, but in normal circumstances can the same be said of Sydney and Melbourne?

Personally, I have great faith in our Poultry Industry. I wish it to expand considerably beyond its present dimensions; not merely in the hands of specialised poultry breeders like yourselves, but on every farm in the State. But if this is to take place, our attention must be centred, not on the over-supplied home markets, but on overseas markets, and particularly the British market. If we succeed in supplying these markets we shall not only benefit ourselves, but be of infinite assistance to the Commonwealth as a whole.

Latest statistics show that our export of eggs for the period 1929-30 have a value of approximately £25,000, that is to say, barely 2½ per cent. of the value of total Poultry Production. It should surely be our aim to expand these values to worth-while dimensions, and the sooner we set about it the better. I am glad to learn that your Association exported 10,000 cases last year and I trust that you will continue to lead the van in this particular direction.

I notice that in 1928 Great Britain imported close on 18 million sterling worth of Eggs in the shell and about two and a half million sterling not in the shell. Here is a market that is surely worth capturing. I am aware that this market makes certain demands, and as potential suppliers it is only common sense that we should aim at meeting these demands. In this direction it has always been the policy of the Department to aim at the 2oz. egg, and I am glad to think that your Association shares our views in this direction. We know, too, that farm eggs are not always up to export standard, and just as it will be our endeavor to induce farmers to produce more and more eggs, both in their own interests and in the interests of the State, so, too, we shall try to impress upon them the absolutely necessity of placing on the market eggs that can safely be exported in the shell. This is very largely a matter of educational propaganda. We have in Mr. Anderson a highly competent young man, who is full of energy, and we can depend upon him to do his utmost for the Poultry Industry in every direction.

On another point, have we not neglected of late the export of dressed poultry, which was of some importance in pre-war days? Great Britain imports between two and a half and three million sterling's worth annually. Why should we not share in this export outlet of produce?

Let me extend my heartiest congratulations to Mr. W. Wiese, of Cabra, for having entered the winning Hen—a White Leghorn pullet—which laid the fine total of 279 eggs. This performance entitles him to hold the 20-guinea Cup presented by your Association. I must also congratulate Mr. C. G. Gavin, of Salisbury, whose team of six birds laid the highest aggregate total of eggs, namely, 1,458 eggs, or an average of 243 eggs per bird.

## TEST WITH WOOD GAS PROPELLED TRACTOR.

TRIALS HELD AT ENFIELD, SOUTH AUSTRALIA.

The Committee on Wood Producer Gas as Applied to Mechanical Transport recently arranged a working test of a tractor driven by wood producer gas. In view of the tests on the general principle of this gas producer, as described in a previous report on tests with a Berliet lorry, the committee decided that the main point for consideration was the relative fuel consumption costs of the wood gas driven tractor as compared with a petrol driven tractor.

Mr. A. G. Pritchard, of Wakefield Street, Adelaide, who had patented and manufactured an improved gas producer for use on tractors and lorries, had fixed one to a 2-ton Cletrac tractor and had been operating it for a period of approximately 180 to 200 hours in experimental and demonstration work, mostly on the farm of the Mental

Wood Gas Propelled Tractor drawing a Six-Furrow Plough.

Hospitals Department, near Enfield, drawing plough, cultivator, and combine at different times. As the Mental Hospitals Department possessed a Cletrac of the same capacity it was decided to carry out ploughing tests on this farm with the two tractors.

The plough at the farm was a six-furrow Shearer set plough, and through the courtesy of Messrs. John Shearer & Sons, Ltd., of Kilkenny, the use of another plough of the same make and size was secured.

To ensure that each tractor was given an equal duty, it was arranged that they should follow each other round the field, and at each second round they should change ploughs. In this way any inequality in draught, &c., of the ploughs, or in the texture, &c., of the land would be adjusted.

The trial was held on Thursday, April 30th, and Mr. R. S. Longstaff, of the Steam Boilers Department, was appointed to supervise the test throughout the day.

Each morning the following routine was observed:—The engine was started on petrol and the furnace fuel was at once lighted by means of a kerosene torch and a small induced draught fan was manually operated to bring the fuel to a state of incandescence.

The engine fuel inlet was then switched over from petrol to wood gas. The whole of the preparatory arrangements were completed and the engine worked on wood gas within a period of five minutes.

The previous test with the wood gas driven lorry having proved that most of our more common varieties of timber produced a satisfactory gas if well dried (*i.e.*, containing not more than 10 per cent. of moisture), the committee did not consider it necessary to use more than the one kind of wood—*i.e.*, dry cut mallee.

The makers of the Cletrac considered that the most suitable speed for the tractor, when ploughing, was three miles per hour. The drivers of both machines were instructed, therefore, that this should be the approximate maximum rate at which they should drive, and the time check on each round of the field indicated that both tractors maintained a regular and satisfactory approximation to this maximum rate.

Mr. Longstaff's report showed that in 5 hours 47 minutes' engine running time (which included the journey from and to the homestead, time occupied in changing ploughs, and 4½ hours' actual ploughing) the petrol driven tractor consumed 8galls. and 1½ pints of petrol (equal to approximately 1gall. 3 pints per hour), and the wood gas tractor 180lbs. of wood and ½gall. of petrol. With petrol at 2s. per gallon and wood cut small at £2 per ton, the respective costs worked out at 16s. 5d. for the petrol tractor and 3s. 8d. for the wood gas tractor, which included 6d. for petrol. On a full 8½ hours' working the wood gas tractor would use no more petrol, as this was only used when lighting up the fire in the generator or after the engine had been standing idle for more than, say, 30 minutes.

Calculated on 8½ hours as an average day's actual working time the daily fuel cost would be—

|                                       | £ | s. | d. |
|---------------------------------------|---|----|----|
| For petrol driven tractor . . . . .   | 1 | 4  | 1½ |
| For wood gas driven tractor . . . . . | 0 | 5  | 2  |

showing a saving in favor of the latter of 18s. 11½d. per day.

Oil consumption was not checked, as previous tests indicated that there was no noticeable difference with either system; if anything, as the wood gas was "dry" it would be expected that the oil consumption would be less with the wood gas tractor than with the petrol.

The question of the relative condition or efficiency of the engines of the two tractors could not be accurately determined. If anything, the one to which the wood gas producer was attached was more worn, as it was older and had done more work.

The foregoing figures indicated that with wood at £2 per ton and petrol at 2s. per gallon, the fuel cost of the wood gas tractor was less than one-fourth of that of the petrol tractor. As the annual consumption of fuel for tractor purposes on a fair-sized farm would range from £100 to £160, it will be seen that this wood gas tractor opens up immense possibilities for economy in farming operations.

TELEPHONE C. 4855-4856.

In this connection the Forest Department furnished particulars of work done by two 2-ton tractors and three No. 30 tractors on the different forests. These five tractors aggregated 5,849½ working hours in the 12 months, using 9,059galls. of petrol (equal to 1gall. 4½ pints per hour), costing £867. Assuming that the ratio of consumption of the two fuels would be the same with the larger tractors as with the 2-ton tractors, the adoption by the Forest Department of the wood gas system would result in a saving to the department of approximately £682 with wood at £2 per ton. As the department had its own saw mills in localities where wood was practically a waste product, it should not cost anything like £2 per ton to cut it into small blocks for the producer.

So far as it was possible to say the risk of fire in the crop or grass from this wood gas tractor was no greater, if as great, as with the petrol or kerosene driven tractor, provided reasonable care in each case was exercised.

The committee had not had the opportunity of comparing the wood gas tractor with the kerosene driven tractor, but as power kerosene cost up to 1s. 5d. and 1s. 6d. per gallon in the outback farming districts, where wood was usually plentiful, there could be no doubt that the wood gas tractor would show to almost equal advantage as it did with the petrol tractor.

The committee inspected the several parts of the producer at the maker's works, and were pleased to note that the whole of the plant was manufactured in South Australia. The members were impressed with the simplicity of the whole outfit and with the quality of the work and material.

In view of the immense possibilities for economy in tractor farming and the very great advantage which would result to the State if many thousands of pounds now sent away for petrol and kerosene could be retained in the State, the committee recommended that one of these wood gas producers be fitted to the tractor used by the Forest Department, at Kuitpo, for further demonstration, and that the Government reduce the registration fees on tractors and lorries propelled by charcoal or wood gas to a nominal sum, as has been done in France.

### PRESSURE IN TANKS.

Replies to the following questions asked by the Blackheath Branch of the Agricultural Bureau were supplied by Mr. T. A. Macadam, Lecturer in Building Construction at the School of Mines:—

Question 1—"Which would cause more pressure in piping for irrigation purposes: a tank holding 5,000galls. of water, built to a height of 6ft., or a tank holding the same capacity with walls only 2ft. high?"

Reply—"The tank holding 5,000galls. of water, built to a height of 6ft., would cause the more pressure.

Question 2—"Would there be more pressure in a 1½in. pipe leading from the bottom of a tank 6ft. high full of water, holding approximately 5,000galls., than there would be with the tank empty and length of 1½in. piping 6ft. high attached to piping in bottom of tank and kept full of water?"

Reply—"No."

Question 3—"Would it increase the pressure to have the piping leading away from the centre of tank in the bottom than, say, a foot in from the side?"

Reply—"When bottom of tank is level the answer is 'No'."

# 3 Harrows in One for the Price of One

The Whakatane Harrow is an all-purpose implement designed in such a way that three exceedingly efficient working surfaces can be secured from the one set of harrows. On the one side a long tine cultivation is provided for, on the other, when drawn one way, the harrow becomes a first-class tripod, and when drawn the other way, as shown in the accompanying illustrations, a manure-spreading, seed-covering harrow, which many skilled farmers and agricultural experts claim as being the finest manure spreading effect so far made possible with harrows.

The Whakatane is designed to treat all classes of country and to suit different types of farming—wheat areas, dairying and mixed farming—being particularly suited for the renovating of pastures and the preparation of seed beds. Its principle of "three harrows in one" gives it an extremely wide scope of usefulness and renders it superior to any of its kind.

## TOBACCO CULTURE.

[By R. C. SCOTT, Supervisor of Experimental Work, and S. B. OPIE, Field Officer.]

(Continued from page 1010, *Journal of Agriculture*, May 15th, 1931.)

## TRANSPLANTING.

In the Adelaide Hills November is the best planting month, although some growers commence operations earlier in the season. Experiments at Mount Barker have shown that mid-November plantings produce the best plants, but much depends on the character of the weather. When a comparatively warm October is experienced the earlier plantings offer advantages, but if cold, wet weather prevails, the later sown plants will not only catch up, but eventually make better growth than earlier sowings. The planting season will therefore vary with the district, and should be as early as the mean temperature of late spring permit. Seedlings whose growth is checked by cold conditions will not make as satisfactory development as later sown plants which have

**Bemis Transplanting Machine.**

gone right ahead after being placed in the field. On the other hand, very late planted seedlings are frequently difficult to establish, because of the hot weather likely to be experienced, and fail to cure out to a satisfactory product. It may therefore be accepted that November is the correct planting month, unless local experience has proved otherwise. If possible, select dull, cool weather, whilst naturally showery weather would be best of all. The seedbeds should be thoroughly watered immediately prior to lifting the transplants, in order to allow them to be pulled from the soil without damage. In soils at all tight it may be necessary to loosen the earth with a digging fork to prevent injury. Select sturdy, well-formed plants with leaves about 4in. to 5in. in length, and with sound root systems. They should be placed in shallow boxes or tins and protected from the sun. The smaller seedlings are left for use later on if required, and, as they have been more or less disturbed, the bed should receive a good watering to pack the soil round their roots. Planting should take place as soon as

possible after the seedlings have been removed from the seedbed. In hot weather avoid the heat of the day, and endeavor to set out the plants in the late afternoon and evening. Under such conditions it would be better if planting were postponed, but if the condition of the seedlings or other causes necessitate going ahead with the work, the young plants should be shaded from the extreme heat of the sun. Material used for this purpose consists of bracken fern, small leafy branches, or sheets of paper. The latter are to be preferred, and in size are about 12in. by 5in. These are arched over the young plants and kept in position by earth placed on each end. Such protection may be allowed to remain for a number of days until the plants are established. When conditions are favorable for transplanting, the work should go ahead with all speed, and, if available, the employment of additional men to complete setting out in a few days is to be recommended. For average soils the usual spacing of plants is about 1yd. apart in each direction. Under this arrangement slightly more than 5,000 plants are required per acre. In more fertile land they are placed closer together in the rows until about 6,000 are planted per acre. The plants may be set out in the field either by hand or special planting machines. A comparison between the two methods is not possible, both being equally efficient, provided that the latter is used only when the soil is in a suitable condition. It is simply a matter of whether the area to be planted justifies the expense of a machine. However, where areas of above five acres are to be planted, the use of a machine is recommended.

A recently transplanted field.

For hand planting the rows are first marked in some manner, probably the simplest being a light wooden rake with large teeth spaced according to the width of the row desired. Usually such rakes carry about six teeth, and are drawn over the surface of the soil to mark six rows at a time. The planter is provided with a small tool to make the holes; usually a round stick or dibber, or a small garden fork. In the holes thus made he sets the plants and firmly presses the soil around the roots and stem. The plants are placed deeper in the ground than they were originally in the seedbed, but not so deeply as to bury the young growing point of the seedling. Unless wet weather is experienced it is advisable to water each plant immediately after setting out, in order to pack the soil closely around the roots, and help it to become established. Dry earth should be raked over the wet soil to act as a mulch.

The machine effects a considerable saving of time, and is capable of planting an area of from two to four acres per day. For best results the soil must be in a fine state of division, and free of rubbish or stones. Three men are required to manipulate the implement—one to drive, one to prepare the seedlings, and the other to plant. The preparer and the planter sit on the seats at the back of the machine. The preparer on the right hand side gets the plant ready and hands to the planter, who pushes it root downwards into the furrow made by the plough. An indicator gives the signal for planting. At the same time an adjustable quantity of water—usually about a pint—is liberated around the plant roots. (Sometimes a liquid manure is applied by adding 6lbs. to 10lbs. of Nitrogenous fertiliser per 100galls. of water.) The parts of such machines consist of a cask to hold the water, a hopper for the fertiliser, a furrow opener and two long curved steel plates which break up the soil and pack it round the plant, together with the necessary mechanism to provide for the liberation of water and distribution of fertiliser. Unless the land is in first class mechanical condition the steel plates cannot do their work effectively, and, therefore, when a transplanter is to be used special attention must be given to the final preparation of the soil.

**The New Idea Transplanting Machine.**

#### **FILLING IN THE BLANKS.**

Several days are required for the young plants to become established, but as soon as possible all that have failed should be replaced by healthy ones freshly drawn from the seedbed. In order to secure a uniform stand and even ripening of the crop, the field should be gone over two or three times during the first fortnight, and plants reset wherever necessary.

#### **AFTER TILLAGE.**

With a leafy crop, such as tobacco, it is obvious that the plants must transpire a considerable quantity of moisture which the roots have to extract from the soil. Every effort must, therefore, be made to maintain the land in such condition that the minimum amount is lost by evaporation. Not only does good cultivation assist in connection with the conservation of moisture, but also the opening up and aeration of the surface soil plays an important part in promoting healthy development of the plant roots. If this air supply is limited, either by water-logging or neglect in tillage, the growth of the tobacco plant is immediately affected. Emphasis must be placed on the necessity

of thorough after tillage of the crop, more particularly under the rainfall conditions frequently experienced during the summer months in this State, when heavy falls may be widely spaced by rainless periods. In such case, adequate tillage is essential to open up the tightly packed soil, promote aeration, create a surface mulch, and retain moisture for the use of the plants.

The first cultivation should be given as soon after transplanting as the visibility of the rows will permit. A horse hoe or double row cultivator may be utilised, thoroughly stirring the soil at a comparatively shallow depth. All weeds must be kept in check, the space between the plants and against the stem being worked over with a hoe. At the same time any damaged plants which are developing several stems should be pruned back to a single growth. The number of cultivations should not be limited, teams being utilised as long as the size of the plants will permit, and from

Effect of good and bad tillage.

then on tillage continued by hand. However, these later workings may be shallower than those given earlier in the season. The number of workings depends entirely upon the character of the season, and whenever weeds or surface crust renders tillage necessary the operation should be carried out without delay, so that the soil is maintained in first class condition throughout.

#### IRRIGATION.

Irrigation water is preferably applied by means of furrows made between alternate rows of plants. Under this system it is essential that the contour of the land should allow for free movement of the water and prevent accumulation in pools, as the tobacco plant is rapidly destroyed under water-logged conditions. Should it not be possible to adopt this method, because of the grade or depth of sand, hoses may be led to various points and the water reticulated in shorter channels. Overhead sprinklers may also be utilised, but as this method is more likely to encourage the development of fungoid diseases, the furrow system is to be preferred if the soil conditions will permit. Means to irrigate at transplanting time ensures a regular take in the field and less replacements. After the final cultivation of the field, furrows about 4in. in depth should be opened up with the horse hoe at the proper distance apart. The water may then be run down these channels and the plants set out on the edge of the open furrow.

During the growing period water should be applied when necessary, and in light irrigations rather than heavy floodings. After every irrigation the land should be thoroughly cultivated as early as possible, so that the moisture is conserved in the soil. The final watering should not be applied later than the topping stage in the growth of the plant. If given later the ripening of the leaves is delayed, and satisfactory curing rendered more difficult. Water should only be applied when needed, as excess moisture results in the production of poor quality leaves, thin and papery in texture, and with coarse ribs.

An indication of the requirement of the plant for water is the condition of the leaves. If, after a cool night, they tend to droop before mid-day, it is clear proof that there is not enough moisture in the soil, and irrigation should then be resorted to.

An Irrigated Crop.

The irrigation of tobacco has not yet been generally adopted in this State, but it is a common practice in Victoria. Where it has been adopted high yields of good quality leaf have been secured, and it appears to us that every grower should endeavor to provide means for watering if a regular crop is to be anticipated. The tobacco grower is placed in exactly the same position as the producer of early potatoes in the Adelaide Hills, inasmuch as experience has proved to him that the provision of irrigation water is an economic proposition, but he only irrigates when the character of the season renders such action necessary. All producers of tobacco in South Australia are strongly urged to endeavor to obtain means for irrigation, thus ensuring regular development throughout the life of the plant, and, consequently, better quality leaves. It is obvious that any check in plant growth will affect quality, and provision for irrigation in low rainfall years, or between long rainless periods, must lead to improvement in this respect.

## SELECTION OF SEED PLANTS.

Before topping the tobacco crop should be carefully examined, and if it is desired to save seed, the plants of outstanding merit should be marked for this purpose. If the selection is being made from a crop grown from purchased seed, only a limited amount should be saved, as the plants may not be fully acclimatised. However, the grower should always be searching for desirable plants which appear to suit his soil and climatic conditions. From the best of these, he would select seed for testing, comparatively with his bulk crop. Shortly before topping several of the best plants should be staked and allowed to develop seed heads. At maturity the individual plant which appears to be best suited to his requirements would be selected. The plant chosen should be healthy, true to type, and early maturing. The leaves should be numerous, of good size, shape, and texture, and appear likely to cure into good quality tobacco. The seed from this plant would be his top selection, and any other grain harvested

Flowering head of selected seed plant covered to prevent cross fertilization.

would be utilised for the ordinary field crop. The seed head should be covered with a cheese-cloth bag, in order to prevent cross-fertilisation. The suckers should be removed, together with a few of the smaller leaves, from immediately below the cluster of flowers. The removal of these leaves prevents the plant from becoming top heavy. The covering should be tied just below the flowering branches, and from time to time must be loosened as the flowers develop. When the seed heads turn brown the grain is sufficiently ripe, and the head may then be cut off with the covering still attached. After careful labelling it should be hung in a dry place until wanted, when the seed may be threshed out by rubbing in the hands.

## TOPPING.

When the plants show signs of bursting into flower the seed head and topmost portion of the stem carrying the smaller leaves should be removed by breaking off with the fingers. This operation is termed topping, and is carried out with the object of improving the quality of the leaf by forcing all the goodness which the plant can extract from the soil into the leaves which are saleable. It is not desired that the energies of the plant should be wasted on the production of seed, whilst very small leaves are of no commercial value.

Topping is really a pruning process, and consists of retaining as many leaves of sufficient size as the vitality of the plant will permit. The number may vary from 4 to 18, with a general average of about 8 or 10. As a rule, the topmost leaf left on the plant should be about a foot in length, and 4in. to 6in. in width. A leaf of these dimensions will, after curing, shrink to about the size limit accepted by manufacturers who, because of the fact that much work in the factory is done as piecework, do not desire small leaves, which necessitate additional labor.

With normal treatment the leaves commence to ripen some three to four weeks after this operation, but with high topping the general life of the plant is prolonged, whilst, on the other hand, heavy topping hastens maturity. Therefore, the height will vary with circumstances. A late crop is usually heavily topped to assist in ripening, whilst an early crop, or one on more fertile land, may be only lightly treated. Further, a tobacco field frequently contains plants in various stages of growth, and in this case variation in topping, such as light treatment of the early plants, allows for more uniform ripening of the leaf.

**Topped Tobacco Plants.**

#### TRIMMING.

This consists of removing the three or four over-ripe, sanded, or damaged leaves from the base of the plant. The operation is advocated by some on the ground that it destroys the hiding places of injurious insects, but it is doubtful if the expense of this work is justified. If left on the plant they shelter the surface soil and protect the leaves above them from damage. The usual time for trimming is when the plants are being topped.

#### DESUCKERING.

Shortly after topping suckers, or lateral growths, will spring from the axis of the leaf with the stem. These should be rubbed off when long enough to handle without difficulty, which is usually when about 3in. in length. If left until they have made more growth they rob food from the leaves which are to be harvested, thus lowering the yield and reducing the quality. The plant is persistent in its efforts to develop sucker growths, on which seed heads would be formed, and it is necessary to desucker two or three times between topping and harvesting. Should wet weather be experienced shortly before harvesting, these lateral growths may be allowed to remain, as they then

absorb moisture and food which would otherwise be forced into the marketable leaves, causing them to become coarse in texture and more difficult to cure to a satisfactory color.

#### RIPENING.

It is essential that the leaf be thoroughly ripe before harvesting, and at times growers have sustained considerable losses by picking the crop before it is fully matured. In the process of ripening the green coloring matter is gradually reduced and the leaf tends to assume a yellowish shade. One of the principal factors in determining the cash value of tobacco is the proportion of bright colored leaf, and, therefore, every grower should aim at thorough ripening, so that the leaves contain as little green coloring matter as possible. Under suitable conditions, and particularly with varieties of the Burley type, the leaves assume a full yellow color on ripening, but as a rule the Virginian types change to a mottled, pale yellowish-green shade. The higher the proportion of yellow the easier the leaf is to cure. On the other hand, the heavier or more fertile soils yield leaves carrying a greater percentage of green color. When fully ripe the leaves tend to droop, become rough, slightly sticky, thicken, and color up as described. The flesh becomes crisp and snaps easily when folded between the finger and thumb, whereas a green leaf carries tissue which is tough and pliable.

A Crop of Ripe Tobacco.

Over-ripeness is indicated by the appearance of brown spots which rapidly increase in area. If this coloring is noticed the leaves affected should be harvested without delay, otherwise they quickly deteriorate in quality.

Ripening commences about three to four weeks after topping, the bottom leaves maturing first and the upper leaves last. In normal weather the ripening period extends over six to eight weeks, and allows for about five pickings from each plant, but with heavy topping the crop matures more rapidly.

Tobacco is only able to properly mature when weather conditions favor the removal of green coloring matter and the fixing of starch in the leaves. For best results the plants should have completed their growth by the middle of February, so that the warmth of late summer and early autumn can bring about this desirable result. Therefore, growers should avoid late December plantings, which are detrimental to good ripening. For the same reason late rains or cool autumn weather, which promote growth, are injurious to the production of good quality leaf.

### FLUE CURING.

Only leaf cured in a proper barn under controlled temperature is saleable. Therefore, every grower must arrange to have his leaf cured, and probably the most satisfactory plan is for each man to erect barns for curing his own crop. It is the most important operation in tobacco culture, as first quality leaf harvested from the field may be completely ruined, or at any rate greatly depreciated in value by bad curing.

Briefly, the object of curing is to promote chemical changes in the leaves which will lead to improvement in color, aroma, flavor, and texture. It is more than merely drying out the leaf, and is an operation which can only be thoroughly learned by practical experience.

So many variations occur regarding the condition of the leaf placed in the barn, climate of the district, variety, &c., that only a general outline of the operation can be given. Therefore the times and temperatures quoted must not be accepted as correct for all cases, but only to serve as a guide. Every grower should keep a complete record of his curing operations so that he has a diary to which he can refer when outstandingly good results are obtained.

### HARVESTING.

It is important that only ripe leaf should be harvested, and personal supervision of the picking operations is greatly to be desired. Green leaf will never cure satisfactorily, the flavor being bitter and objectionable. Palatable tobacco can never be produced, and no process of curing or manufacturing can overcome the objectionable features. Enough leaves of uniform ripeness should be available for filling the barn in one day. A barn containing leaf in various stages of maturity, even if well cured, will grade irregularly, and, therefore, will not produce maximum quantity of top grade leaf. Tobacco should not be harvested immediately after rain, as washing causes loss of essential gum which puts body and elasticity into the leaves. However, nature quickly restores this substance, and after a few days it is quite safe to continue harvesting. For the same reason leaves should not be picked when either wet with rain or with heavy dew. On the other hand, leaf harvested in extreme heat is tending to wilt, and under such circumstances is inclined to cure out with permanent greenish patches. The best time for picking is on cloudy, warm days, when the leaves are dry and slightly sticky or gummy. The single leaf system of picking should be adopted, and the leaves removed as they ripen from the bottom of the plant upwards. As many as four leaves may be ready at the one time, and the plant is visited at intervals until all have been harvested.

Care must be exercised in handling, as leaves which are bruised or stacked for any length of time will not cure satisfactorily. A good plan is to lay the leaves on sheets of hessian about 6ft. square, and when filled gather up by the corners and place on the trolley or dray.

In the Adelaide Hills the harvest usually extends from about mid-February to mid-April. Crops ripening later than this are of poor quality and difficult to cure.

### TYING.

After the leaves have been conveyed to the barn they are fixed to sticks ready for hanging. The sticks used for the purpose are of such length as to rest across the bearers without overlapping, and, as a rule, in most barns are approximately 4ft. They may be of any hardwood, sometimes wattle sticks, but preferably sawn battens either 1in. by 1in., or 1in. by 2in. in cross-section. When the leaves are attached by

string, battens of the former dimensions are secured, whilst if fixed on wires the sticks of greater width are utilised in order to prevent tipping should the leaves cure out to a greater weight on one side than the other. The wired stick method for attaching the leaves is preferred, as under this arrangement they are evenly spaced, and allow for free movement of air, thus avoiding danger of discoloration from sweating. Sharpened No. 12 gauge galvanized steel wires are threaded through holes on the stick to project about 7in. on either side. They are spaced about 6in. apart,

Small Curing Barn, Experimental Field, Mount Barker.

and a similar distance from the end. About eight leaves are threaded on each. When complete the stick carries from 110 to 130 leaves, and is placed in the barn so that the wire points almost touch those of the next. The stringing system is more popular, as it allows for quicker work and easier handling of small leaves. Thin twine is used for the purpose. It is fixed about 4in. from the end of the stick, and the leaves in bundles of two or three, according to the size, tied on alternate sides. A bunch is placed close to the stick, and the twine looped round the stems. The next bunch is placed on the opposite side and the string carried across to loop round the butt in the form of a figure 8. This is continued along the length of the stick, each bundle about 4in. apart, making about 25 in all, and the string finally tied or slipped in a slot at the opposite end. •

## BARNs.

Curing barns can be built of stone, brick, concrete, galvanized iron, wood, &c., but whatever the material utilised, special attention must be given to the means for heating and ventilating.

As the curing process demands great and even distribution of heat, two furnaces are preferable to a single fire. Details of the arrangement are shown in the accompanying plans. To ensure humid conditions during the first stages of curing, the building should be as airtight as possible, and the ventilators and door tight fitting. However, in the later stages, a free draught of air is required. The ventilators should be sufficiently large for this purpose, and also permit of easy regulation. Various systems of ventilation are in vogue, some curers favoring a complete ridge cap vent, and others a butterfly type, or ordinary hinged ventilator, but whatever system is adopted it is important that the operator should have complete control over the opening or closing

Tobacco Barns, Paris Creek.

of the vents. As a rule barns are approximately 20ft. in height, and 12ft. to 16ft. square on the base. Such dimensions allow the bulk of the leaf to be hung where the humidity accumulates, whilst the chimney-like shape is conducive to the creation of a draught. With a lower roof the proportion of space lost is increased, since leaf cannot be hung closer than about 7ft. from the flue pipes. A modification of this style is what is known as the Dug Out Barn, in which a hole is taken out from the ground about 6ft. deep over the full floor space, and then walled up with concrete or other material. On this the barn is erected to a height of 12ft. to 14ft., and the door made at ground level opposite the tiers on which the leaf is hung. The fireplace is constructed on lines similar to those used in lime kilns, and the vents situated a little higher than is the case with high barns. In this type a considerable saving of labor is effected when filling and emptying.

In this State galvanized iron is the most popular material used in the construction of a curing barn, the building being lined with plain galvanized iron, and the hollow wall space filled with sawdust or charcoal.

A building erected according to the plans and specifications on the following pages is capable of handling the leaf from a 4 to 5 acre crop, whilst a 16ft. by 16ft. by 20ft. high building could cope with the produce from 6 to 8 acres.

14 sheets of 9ft. corr. galv. iron, 24 gauge, roof.

48 sheets of 7ft. corr. galv. iron, 26 gauge, sides.

28 sheets of 6ft. corr. galv. iron, 26 gauge, sides.

62 sheets of 6ft. x 3ft. plain galv. iron, 26 gauge, lining and ceiling interior.

15ft. of 14in. ridge capping.

30ft. of 5in. O.G. guttering.

96ft. of 12in.d-24 gauge galv. iron piping, and 73ft. for alternative scheme.

*Doors.*—Door opening, 6' 8" x 4' 0", for double or single doors.

*Windows.*—2 fixed windows, 4' 0" x 3' 0", 4-light.

*Furnace.*—May be built of bricks or suitable stone.

*Concrete.*—Barns constructed with this material are not subject to fire, nor are they affected by climatic changes. They maintain an even inside temperature with little attention, and form a very substantial and dual purpose farm improvement. Concrete barns, however, are liable to cause trouble, because the walls have a tendency to absorb moisture.

With a concrete barn, special care should be exercised in placing the reinforcement rods, which are set at 12in. centres both ways, and well turned at the corners and tied.

Concrete mixture: 1 - 2 - 4, with walls 6in. thick.

7cwts. ½in. reinforcement rods and 4in. x 2in. cross bearers are required.

Roof, furnace, flues, doors, and windows similar to wood-and-iron specification.

*Stone.*—40 cubic yards of masonry are required, with 4in. x 2in. cross bearers.

Roof, furnace, flues, doors, and windows similar to wood-and-iron specification.

*Weatherboard.*—This is quite a suitable material and can be cheaply erected, because in most cases the farmer is able to do the construction work. It is important, however, that a barn of this description be lined. It is suggested that building paper, placed in position before the boards are nailed, be used for this purpose. With weatherboard, great care must be taken to avoid danger from fire and as a precaution, the first few feet over the fireplace should be constructed with bricks.

For the above plans and specifications we are indebted to Mr. T. O. Carlisle, of the Hydraulic Engineer's Department.

#### FILLING THE BARN.

A standard barn of 12ft. by 12ft. by 20ft. will take approximately 300 sticks, each placed about 8in. apart on the tiers, and will cure from 300lbs. to 500lbs. of tobacco, according to the length and quality of the leaf handled.

It is most important that the leaf should be picked and the barn filled in the one day, otherwise the curing will not be uniform. If this is not possible, all leaf should be picked on the first day ready for filling in the second, and the last harvested placed in the top of the barn. However, unhung leaf kept overnight should be stacked in single rows, not more than a few inches in height, in order to prevent heating.

Should there be any lack of uniformity in ripeness, the more immature leaves should be hung in the top tiers, where the humidity is greater.

Log Curing Barn.

#### THE CURING PROCESS.

This involves three distinct stages, namely:—

1. Yellowing of the leaf.
2. Fixing the color.
3. Drying the leaf.

Immediately after the barn is filled the fires should be started, all ventilators closed, and two thermometers (a wet and dry bulb) hung in the centre of the first tier of leaves. The two thermometers are necessary so that the temperature and humidity of the barn may be ascertained. It is the humidity which is the most important factor in the process of yellowing the leaf. Both thermometers should be capable of reading to 200° F. and attached to a board or solid foundation. They should be set about 2in. apart, making sure that the readings are level, and the mercury bulb of one wrapped with woollen wick leading to a small bottle of water fastened about 1in. below the thermometer. The difference between the readings will then show the humidity of the atmosphere.

It is of advantage if the process of curing can be commenced in the evening, as then the various stages usually occur at more convenient times. Further, it is difficult to accurately gauge the color of the leaves in an artificial light, as they always appear more green at night.

**Yellowing the Leaf.**—Under average conditions this will take about 40 hours, but will vary within very wide limits. The fires having been started the temperature, as indicated by the dry bulb thermometer, should be raised to about 90° F., or 10° F. above the outside temperature. The time taken to reach this heat should be from four to five hours. About seven hours after the lighting of the fires the leaves should commence to sweat, and create a sufficiently humid atmosphere to cause the wet and dry bulb thermometer to register a difference of 3° F. to 4° F. If the barn is airtight, the leaves may supply sufficient moisture, but if such is not the case, artificial steaming must be provided. The usual method of raising the humidity is to place wet bags over the flue pipes, or to dampen the floor. The former is to be preferred, because, in the case of the latter, any excess moisture cannot be quickly removed. Owing to the danger from fire if the wet bags are allowed to dry right out, they should not be laid

Barn in the process of erection, built of slabs of timber and mud.

on the pipes, but suspended on a strip of wire-netting erected immediately over the flues. In addition, the wire-netting lessens the risk from fire, as it will catch leaves which may fall from the sticks on to the hot piping. The temperature must be kept at 90° F. until the leaf commences to yellow at the tip and round the edges. It should then be raised at the rate of 2½° F. per hour till it reaches 95° F., where it should be held until the yellowish shade spreads from the edges towards the centre of the leaf. When this occurs the temperature may be raised at the same rate to 100° F. This heat must be maintained until the yellow color is more pronounced and the leaf assumes a light pea-green shade. It is most important that the curer should not hurry past this stage, otherwise the green matter will become fixed in the leaves and cause a marked depreciation in value. On the other hand, if allowed to become too yellow the leaf may not be able to hold this shade when passing through the other stages, and become a dark-brown color before the drying out is complete.

**Raising the Color.**—When, in the judgment of the curer, the majority of the leaves have yellowed sufficiently, the temperature may be raised to 110° F. at the rate of about 2½° F. per hour. At 105° F. the top vents should be lifted a little, and at 110° F.

both top and bottom vents slightly opened. At the commencement of ventilation some of the humidity will be lost, and the difference in the readings of the wet and dry thermometers should increase at the rate of 2° F. for every 5° F. rise in temperature. Thus at 110° F. the difference should become 7° F. to 8° F. The barn must be held at this temperature until there is only a slightly greenish tinge at the base of the leaves, whilst the tips have curled and become dry. Having attained this shade, the next step is to fix the color. This is the most difficult period in the process of curing, as experience is needed to be able to adjust the heat and ventilation so that the moisture is removed just as quickly as it can escape from the leaf. Should the curing be proceeding too rapidly, dark-reddish colored patches will appear, whilst if too slowly, moisture will

Interior View of Tobacco Curing Barn.

condense on the leaves and give rise to greyish-brown blotches. This latter marking is known as sponging, and the former as reddening or scalding. Whilst sponging is undesirable, it is preferable to scalding, and is caused by insufficient temperature and ventilation. On the other hand, scalding is due to excessive ventilation and too rapid increase in temperature.

In the process of fixing the color the top and bottom ventilators must be gradually opened, and the temperatures slowly raised to 115° F. This heat is maintained for from four to six hours, and then increased to 120° F. and held for the same time. It is next brought to 125° F., and finally to 130° F., where it is held until the whole of the blade of the leaf is dried out. During the period of fixing the color, close attention must be given to the work. With correct temperatures and ventilation the tips of the leaves will feel soft if brushed with the hand, whilst if sticky the ventilation

should be increased. Should there be signs of scalding, which first appear on the edges and thin parts of the leaf, the temperature should be lowered by several degrees and kept there for three to four hours before being again raised.

*Drying the Leaf.*—At this stage only the larger veins and midrib are moist, the remainder of the leaf being dried out whilst fixing the color. The bottom vents must be partially closed and the temperature raised at the rate of 5° F. per hour until 170° F. is reached, where it is maintained until the midribs are thoroughly dry. This condition is indicated by the ease with which they will snap when leaves taken from the corners or sides of the barn, where drying is slower, are tested. Any neglect in this direction will result in the development of mould in the bulked leaf, and if this is noticed it must be immediately returned to the barn and dried out.

CURING TABLE.

| Condition.                            | Temperature.<br>Degrees F. | Time.<br>Hours. | Remarks.                       |
|---------------------------------------|----------------------------|-----------------|--------------------------------|
| <i>Fill barn in one day</i> . . . . . | —                          | —               | Light fires in evening.        |
| Ripe fresh leaf . . . . .             | 90                         | 4               | After lighting fires.          |
| Sweat commences . . . . .             | 90                         | 6-7             | After lighting fires.          |
| Leaf yellow round edges . . . . .     | 90                         | 12-30           | Humidity 3° F. to 4° F.        |
| Yellow spreads . . . . .              | 95                         | 6-12            | Humidity 3° F. to 4° F.        |
| Yellowish pea-green color . . . . .   | 100                        | 6-24            | Humidity 3° F. to 4° F.        |
| Yellow more pronounced . . . . .      | 105                        | 2-6             | Open top vents slightly.       |
|                                       |                            |                 | Humidity 5° F. to 6° F.        |
| Practically yellow . . . . .          | 110                        | 2-6             | Humidity 7° F. to 8° F.        |
|                                       |                            |                 | Open top vents more.           |
|                                       |                            |                 | Open bottom vents a little.    |
|                                       |                            |                 | Gradually open vents.          |
| Fixing color . . . . .                | 115                        | 4-6             |                                |
| Fixing color . . . . .                | 120                        | 4-6             |                                |
| Drying web . . . . .                  | 125                        | 4-6             | Ventilators open full.         |
| Drying web . . . . .                  | 130                        | 4-6             |                                |

## VARIATIONS IN CURING.

The above table is only intended to serve as a guide, and in practice many variations will occur which must be dealt with by the curer. Leaf which yellows well in the field, as is the case with some varieties, particularly when grown in light-textured soils, can be cured quickly, since it does not require the same length of time to assume the desired color as does greener mottled leaf of heavier texture. Leaf picked during wet seasons or in moist atmospheric conditions is difficult to dry out, and may give rise to excess humidity. Under such circumstances the top vents must be opened early and the moisture driven off. As the yellow color commences to appear, so should the ventilators be gradually opened, with the result that the drying and curing should be both going on at the same time. In consequence, the temperature should not be raised above 110° F. to 120° F. before the best possible color is obtained. Again, late ripening crops have frequently to be maintained at about 85° F. for 48 to 72 hours until the yellow color appears.

## CONDITIONING LEAF.

On the completion of curing the leaf will be dry and brittle, and must, therefore, be conditioned before it can be handled without damage. Wet bags placed over the hot flue pipes will give rise to steam, which is quickly absorbed by the leaves, thus allowing them to be removed about two hours later. If the barn is not urgently required for the next cure, the fires should be drawn and all vents, doors, and windows opened to the night air, when, under ordinary climatic conditions, the tobacco will be sufficiently pliable for handling next morning.

(To be continued.)

## FARM BACON CURING.

[By R. BAKER, R.D.A., Dairy Superintendent, Roseworthy Agricultural College.]

(Published at the request of the Owen Branch of the Agricultural Bureau.)

The purpose of this article is to give in a very concise and brief form the directions needed by those inexperienced in the art, to enable them to attempt the home curing of bacon.

No attempt is made to elaborate the more technical details of the trade side of the subject, which abounds in refinements. By following these instructions, however, the average farmer should be able, with very little expense for equipment and materials, to turn out a thoroughly palatable product of sound keeping quality.

### CLASS OF PIG.

The pig should be healthy, in good condition, and gaining weight at the time of slaughtering. The live weight should be from 160lbs. to 175lbs., which gives a dressed weight of approximately 110lbs. to 125lbs. Heads and trimmings account for a loss of about 20lbs., and there is a loss during curing of approximately 20 per cent., so that the weight of the final product ranges from 75lbs. to 85lbs. per pig in the range of live weights specified.

### SLAUGHTERING.

Before slaughtering, the pigs should be starved from 12 to 24 hours, and care should be taken to avoid rough handling, which causes bruises and discoloration in the finished article. Stun with any blunt instrument and cut the throat to allow of free bleeding. Care should be exercised in doing this to avoid sticking the inside of the shoulder, or otherwise injuring the flesh internally.

### SCALDING.

A vat of some kind is necessary, and this should contain sufficient water to cover the carcass. The temperature of the water should be 145-150 degrees Fah. In the absence of a thermometer a common test is to drop in a drop of fresh blood which will immediately coagulate if the water is hot enough. Care must be taken, however, not to have the water too hot. Keep the carcass moving while in the water and scrape off the bulk of the hair and the thin outer skin by using a scud or scraper. Finish scraping with a sharp knife in the presence of cold water. Remove hoofs with any sharp-pointed instrument.

### DRESSING.

The carcass is then hung for dressing. Remove the flare or abdominal fat as well as the entrails, &c. Allow to hang, say, overnight for the purpose of cooling off and setting.

### CUTTING UP.

The head is removed by cutting across lin. behind the ears, and the backbone by cutting down on either side with a saw or chopper. If for sides, merely trim up and remove the trotters; if curing in pieces, in addition, cut off the ham to a convenient size and shape, cut off the shoulder, and from the remainder remove the ribs and make into a roll. Trimmings require removing from all pieces. If dry salting is to be adopted it is as well to break the joints of the ham to allow freer access for the salt.

### EQUIPMENT FOR CURING.

A clean wooden barrel is a suitable vessel in which to cure the meat when using brine. For dry salting a clean cement floor or strong table is suitable for stacking the flesh upon. The temperature of the room should not exceed 60 degrees Fah.

**PRESERVATIONS.**

The pickling mixture consists of salt, saltpetre, and sugar. Salt alone has hardening effect and tends to bleach the natural color. Saltpetre preserves the natural color, but should not be used to a greater extent than 1lb. to 20lbs. salt. Sugar has a softening effect and imparts flavor. Baking powder used in small quantities will sweeten brine and prevent it from spoiling during warm weather.

**DRY SALTING RECIPES.**

1. 10lbs. salt, 4ozs. saltpetre to every 100lbs. of meat.
2. 10lbs. salt, 4ozs. brown sugar, 2ozs. allspice, 2ozs. saltpetre to every 100lbs. flesh.

**BRINE RECIPES.**

1. 20lbs. salt, 1lb. saltpetre, dissolve in 10galls. water and allow to cool before using.
2. 20lbs. salt, 1lb. saltpetre, 8lbs. brown sugar, 2ozs. allspice. Boil in 10galls. water and use when perfectly cold. Allspice should be in linen bag.

**CURING.**

First rub with a mixture of salt and saltpetre once a day for first three days, placing the pork in a stack with flesh downwards to allow draining of blood. After the third day either practise dry salting or brine curing.

**DRY SALTING.**

Sprinkle the pieces each day with the recipe, placing them in a stack with the flesh upwards, change the position of the pieces each day, working the salt into the flesh by working the joints of the hams and shoulders. It generally takes three weeks to cure by this method.

**BRINE CURING.**

Pieces are placed in brine after the third day, changing the position each day and working the joints. This also takes three weeks.

**SMOKING.**

The flesh is prepared for smoking by removing all undissolved salt and allowing to soak in cold water for 24 hours. Hang in a cool draught until dry. Surround the meat with a heavy smoke at a low temperature for two to four days. Hardwood sawdust makes good, clean smoke. A firepot outside, with flue to carry the smoke to a large box or barrel, will be found convenient. Care should be taken to prevent meat from becoming overheated.

## **TOBACCO SEEDLINGS.**

One of the main difficulties in tobacco growing is the raising of the plants from the seed. Why not leave this to the experts and save disappointment?

**The Smyrna Figs Estates (Barmera) Limited**  
**CAN SUPPLY YOUR NEEDS.**

A letter to the Manager, P.O. Box 23, Barmera, will reserve your tobacco plants and give you any information you require.

**EARLY APPLICATION IS NECESSARY.**

## RED COMB EGG ASSOCIATION.

## OFFICIAL SINGLE TEST.

## EGG-LAYING COMPETITION, 1931-32.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1, White Leghorns—141 birds. Section 2, Black Minorca—9 birds. Section 3, Black Orpington—57 birds.

Twelve Months Test. To start on April 1st, 1931.

## Section 1.—White Leghorns.

## APPLE CULTURE.

*{Notes from an address delivered by Mr. H. N. Wicks (Vice-Chairman of the Advisory Board of Agriculture) before the Ashbourne Branch of the Agricultural Bureau.}*

In the course of his remarks Mr. Wicks said the apple industry, as a wealth producer, ranked about fifth in importance, and yet it did not receive the consideration it deserved in matters of research. The steps by which the present state of the highly developed commercial apple had been achieved were outlined. He traced the development from the natural order, *Pomaceæ*, which contained several genera, one of which included the hawthorns, one the quinces, one the mountain ash, and one the pears, apples, and crabapples, the latter being the genus *Pyrus*. Within this genus were several species, nearly all of which were native to the old world, and the species from which commercial varieties had emanated was known as *Pyrus Malus*. The methods of development by seed variation through the medium of pollination were roughly outlined and the development of present-day varieties touched upon.

Apples had been in common use from earliest times when the primitive crabapple was sought after as much for the beverage, cider, obtainable from it, as for the fruit. The number of varieties now ran into thousands. Nature seemed to retrogress from the advanced types if allowed to propagate along natural lines, and for one good seedling obtained many hundreds of useless varieties were the usual result. However, occasionally a good seedling was sometimes found, *e.g.*, Granny Smith.

In the development of new varieties by hybridization, scientific work was necessary to assist, because individuals could not usually afford experimenting in an extensive way. At the same time, each grower had to test certain practices to suit his own peculiar conditions, because identical varieties would sometimes exhibit remarkable changes in different localities. The "off-year" was giving concern to exporters, and the surmounting of this obstacle would enable a more uniform overseas supply to be sent forward, thus allowing shippers and buyers to operate with more confidence and greater satisfaction.

### LOCALITY AND SOILS.

With regard to suitable conditions for apple culture, the following applied:—Rainfall, 25-40in. A wide range of soils would grow apples successfully, but a good free loam with a good clay subsoil at about 1ft. to 15ins. was desirable, although with a good subsoil a soil of sandy, light nature would often produce a fine apple orchard. Good drainage was an essential; sourness in the soil must be avoided at all costs. The aspect of the orchard should be one facing east or north, or even to north-west not detrimental. To lay out the orchard the breaking up of the soil deeply was necessary, and it was preferable to leave the land fallow for a considerable time. Planting was best done after a good soaking rain in early winter, except in excessive rainfall districts, when spring planting was better. A wide headland, at least 30ft., should be left to provide adequate working facilities. Distance apart should be from 20ft. to 23ft., and the speaker favored square planting. An apple orchard should be a 50-year investment at least, and the preliminary work was, therefore, worth a great deal of consideration.

Pruning for the first five years should be hard, for during that time the structure of the tree was formed. Codlin moth was the worst pest, but with the help of the scientist, Mr. Wicks was hopeful that a parasite would be found to combat it, as had been done in the case of woolly aphis. When planting, care should be exercised to include varieties to cross-pollinate one another, for by this method better fruit, more of it, and less windfalls were obtained.

Mr. Wicks stated that it was possible for Australia to materially increase her apple cheque, and by attention to shipping good quality fruit and more efficient marketing methods, this was not only possible, but was the logical step to achieve, gifted as they were by favorable climatic conditions and soils suitable for the production of the finest apples, comparable with the best produced in any part of the world.

In answer to questions, Mr. Wicks said that the advent of bitter pit in Cleopatras after pruning was causing a deal of thought, and there, again, the value of research work was emphasised. The method recommended by some growers was to prune on the off-year so that a smaller quantity would be affected, and by the time the heavy crop was carried, the effects would not be so apparent. Other growers recommended merely a very light annual thinning, to keep the tree in shape.

Mr. Wicks believed that the good market in England for South Australian apples was because of the high standard of quality maintained during the past few years. He stated that the iodine test for ripeness was not always successful, and an experienced grower could tell by the appearance and the feel of the fruit when it was ready to pick and pack for export. Varieties recommended for this district were Cleopatra, Dunn's, Granny Smith, and for colored varieties Jonathan and Statesman. For a manurial dressing at planting, he favored bone manure, because the good effects were felt for several years.

# Scientific Farming!

**THAT** is the only proper response to present troubles—**THAT** is the road to solvency and restored prosperity. . .

Economies are necessary, but to cut the application of super in this years farming effort would be a fatal mistake. .

Science and Economy dictate the liberal use of

## W.M.L. EXTRA HIGH-GRADE SUPER

for it lowers costs by increasing yields.

[BATCH]

## STATE OF SOUTH AUSTRALIA.

## FINAL RESULTS OF CEREAL AND HAY HARVEST, 1930-31.

[By W. L. JOHNSTON, Government Statist.]

Wheat, 34,871,526 (23,345,093 bush.); average, 8.34 (6.40) per acre.

1. *Acreage Cropped*.—The acreage sown for all purposes with Wheat, Barley, and Oats aggregated 5,293,882 (4,827,861) acres; increase, 466,019 acres. Distributed as follows:—For Grain—Wheat, 4,180,513 (3,645,764) acres; increase, 534,749 acres. Barley, 251,957 (305,316) acres; decrease, 53,359 acres. Oats, 218,416 (277,923) acres; decrease, 59,507 acres. Hay (Wheat, Barley, and Oats), 601,240 (534,886) acres; increase, 66,354 acres.

2. *Failures*.—Owing to adverse seasonal conditions considerable areas completely failed. Out of 5,293,882 acres sown, 375,000 acres are estimated to have failed for the purpose for which sown. Of this area only 42,000 acres were profitably fed off, the balance of 333,000 acres being a complete failure.

3. *Production*.—Wheat—34,871,526 (23,345,093) bushels; increase, 11,526,433 bushels; average per acre, 8.34 (6.40) bushels. Barley—3,960,929 (4,656,254) bushels; average, 15.72 (15.25) bushels. Oats—2,080,311 (1,564,287) bushels; average, 9.52 (5.63) bushels. Hay—621,171 (431,044) tons.

4. *Benefits of Fallow*.—Of the total wheat crop, 23,718,522 (18,904,280) bushels were produced from fallow land, and averaged 11.05 (9.07) bushels per acre; whilst the remainder, 11,153,004 (4,480,813) bushels, was from land not fallowed, and only averaged 5.48 (2.84) bushels per acre, resulting in an aggregate average of 8.34 (6.40) bushels per acre.

5. *Exportable Surplus*.—After making the usual allowances for Seed Wheat and home consumption, it is estimated that 28,000,000 bushels of Wheat are available for export. Of this quantity over 14,000,000 bushels have been exported. The mean value of over-sea exports of Wheat and Flour for the five years ended 1929-1930 was £5,540,076 and of Barley £201,920. For the 10 months of the year 1930-1931 the export values are:—Wheat and Flour, £2,205,642; Barley, £288,463.

**MEGGITT'S LINSEED MEAL.**

The seasonal reduction during certain months of the year in the output of milk, cream, butter, and cheese, can definitely be checked by the use of Meggitt's Linseed Meal.

Meggitt's is a highly concentrated food, rich in essential milk producing and body building protein, and conditioning linseed oil in the correct proportions.

Sold in any quantity, from one bag (100lbs.) upwards.

Obtainable from any Dairy Produce Factory, Grain or Chaff Merchant, or direct from—

**ELDER, SMITH, & CO., LIMITED,**  
SELLING AGENTS IN SOUTH AUSTRALIA.

## ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR JUNE.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

Planting should be completed as soon as possible. It is much easier to handle the young trees if stakes are placed in the exact position to start with; then put the young tree against the stake and proceed with the filling in. Do not go on with the planting in the rain or if the filling is wet and sodden. The young trees may be pruned before planting, but it is preferable to do it later on. If details are required, consult the Instructor for your district.

Get ahead with the pruning; clear up all broken or dead limbs first, and then make the pruning as light as possible. A minute or two will remove a big limb, but it will take years to replace it.

Clean up trees and remove any shelter for codlin moth larvae; hollows in old trees may be filled with concrete after removing decayed matter. On wet days hunt out codlin larvae in sheds and boxes; everyone killed will lessen the damage in the summer.

Rough up the soil, especially about the trees, so as to get full benefit of all the rain which falls, but arrange for disposal of excess water and prevent washaways.

Citrus trees need watching for "brown rot"; keep limbs up from the ground and spray with Bordeaux mixture on the first sign of trouble. Keep aphids down.

Clean up celery beds; burn, or bury refuse deeply.

Dig strawberry beds and finish planting; do not allow water to lie about the plants.

Olives will be ready for gathering; do not allow them to waste as usual, but get someone to take the crop if you do not value it.

Tomato houses will be got ready for planting. Use only seed from known healthy plants and start them in sterilised seed beds; on no account plant out weak-looking seedlings.

Apples in cold store require watching and sorting out. Generally, they are not keeping very well this year.

### *A Few Observations on Codlin Moth.*

The small crop of apples this season suffered severely from the moth despite the continual use of arsenate of lead spray. Some growers blamed the quality of the material. I was shown fruits thickly coated with arsenate of lead, and successful entrances had been made by the caterpillar through thick accumulations of the spray. This would tend to bear out the contention of the orchardist that the spray was not effective. The only explanation was that the caterpillar was averse to eating through the spray material and had cleaned a place to start before perforating the skin of the fruit. One apple exhibited to me had twenty entrances.

Other growers were inclined to blame their neighbors for being negligent, but examination did not bear this out. One contended that it was impossible to do good work except by using a power pump at high pressure, 250lb. to 300lb. per square inch. I consider that this contention is wrong, as a good hand pump should do equally good work, though not so speedily or cheaply as the power pump. The use of white oils was variously commented on, some saying that the oil was useless and damaged the fruit. Others said that for the amount of good it did it was too costly and so was not worth using, whilst others were quite satisfied that the use of the oil was a distinct benefit. Experiments thus far conducted with oils at the State Orchard were not wholly favorable. The orchard with the least affected fruit was dusted, and dusted well.

Operations as at present conducted were not what we needed, and something more was required to successfully check the work of the moth, and new methods or additional methods must not increase the costs, which were already almost prohibitive.

The most hopeful proposition was the introduction of the parasite *Trichogramma minutum* (*Tricky*). Eight years ago this wasp was operating in California, and a considerable quantity of writing had been done about this little helper, recent reports being distinctly encouraging. Another method worthy of testing would be the use of some material as a spray or dust or smoke which would have a repellent effect on the moth and drive it away from the trees. Natural parasites are perhaps available here. I had been asked to arrange to destroy some "rotten" old trees on a deserted property in the scrub, about two miles away from the orchardist who complained about them. On examination of the trees, which carried a medium crop of low-quality fruit, I could not find any codlin-infested fruit. This was not an isolated experience. At the present season all that was left for us to do was to intensify the work of destroying the larvae of the moth by clearing away all harbors like loose bark or decaying parts of the tree. Windfalls should not be allowed to remain about the orchard, and boxes and storerooms should be thoroughly cleaned up. I am convinced that second-hand boxes were the main source of infection. The various brands of arsenate of lead were well made and true to label.

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on May 27th, there being present Messrs. F. Coleman (Chairman), H. N. Wicks (Vice-Chairman), A. M. Dawkins, A. L. McEwin, P. H. Jones, S. Shepherd, P. J. Baily, Professor A. J. Perkins (Director of Agriculture), Dr. A. E. V. Richardson (Director Waite Research Institute), Mr. W. B. Birks (Principal Agricultural College, Roseworthy), and H. C. Pritchard (Secretary). Apologies were received from Messrs. G. Jeffrey and H. S. Taylor.

*1931 Annual Congress.*—The Secretary intimated that approval had been obtained to hold the Forty-second Annual Congress of the Agricultural Bureau during Show week, and that His Excellency the Governor had consented to deliver the opening address.

*Formation of Branch of Bureau at Belvidere.*—An application was received from residents of Belvidere asking approval for the formation of a Branch of the Agricultural Bureau in that district. Because of the close proximity of the proposed Branch to a Branch already actively working, the Board withheld its decision pending a report from the General Secretary, who was instructed to convene and attend a meeting of each of the Branches concerned and report to the Board.

*Life Members.*—The names of Messrs. W. L. Brown, A. Spriggs, F. W. Jericho, G. A. Dreckow, and R. B. Deer, of the Yandarie Branch, were added to the roll of life members of the Agricultural Bureau.

*Leave of Absence.*—The Secretary was instructed to make application to the Minister of Agriculture for leave of absence on behalf of Mr. G. Jeffrey owing to illness.

*Letter of Sympathy.*—Members learned with regret of the continued illness of Mr. H. S. Taylor, and it was decided to send a letter of sympathy to Mr. Taylor and expressing the hope that he would soon be restored to good health.

*New Members.*—The following names were added to the rolls of existing Branches:—Warrambo—H. F. Chilman; Blackwood—G. Armstrong, W. J. Hargreaves; Longwood—C. Palmer; Greenock—A. F. Giles; Brinkley—E. L. White; Currency Creek—L. C. Collett, R. L. Stephens; Kangarilla Women's—Mrs. A. Strickland; Upper Wakefield—Harry Welke, Gus Welke, Ewald Welke, Alfred Welke; Pygery—J. F. Heylen; Mangalo—F. Coles; Riverton—J. F. Smith, G. B. Payne; Scott's Bottom—P. C. Mitchell, O. H. Ringvall; Taragoro—Vernon Guy; Renmark—J. W. Duggin.

Number of members, 8,507; number of Branches, 305.

*In Committee.*—Several other items in the agenda were taken in Committee.

## DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on June 1st:—

**BUTTER.**—The farming community generally are giving more attention now to dairying and the side lines of the farm owing to the prices for cereals having fallen to such an extent. The result is that increasing quantities of cream and butter are coming forward each week, and this State has already a surplus for export, which is going forward by the *Jervis Bay* this week. Such early shipments are almost unprecedented, and the propitious weather conditions which have continued throughout the season should result in record quantities being exported overseas from South Australia. A feature in the increased production, however, is the large quantities of store and collectors' butters being marketed, and the reason for this is because no levy has to be paid by makers on same, whereas factory butter is subject to a levy. As milled butter cannot be exported, except at very low prices, values for store and collectors' butters are now considerably easier in price, although factory butters remain steady. Choicest creamery fresh butter, in bulk, 1s. 4½d.; prints and delivery extra; second and third grades, 1s. 2½d. (these prices are subject to the stabilisation levies); well-conditioned store and collectors, 9d. to 10d.

**EGGS.**—Production as usual at this time of the year declined rapidly, but now is showing a slight increase. Supplies are more than sufficient for local needs, and small quantities are going forward to Melbourne and Sydney each week. Rates are steady. Ordinary country eggs, fresh hen 1s. per dozen; duck, 1s. 1d. per dozen; selected, tested, and infertile higher.

**CHEESE.**—The consignments from the factories during the past few weeks have been small, and it will be several weeks yet before any marked increase in supplies is possible, as in the south-eastern parts of the State the cooler weather retards the growth of the pastures. Values are firm in consequence of the shorter supplies. New makes, large to loaf, 7½d. to 8½d. per lb.; semi-matured and matured, 10d. to 11d. per lb.

**ALMONDS.**—Good supplies continued throughout the month, and values hardened. This, however, did not in any way cause demand to slacken, and ready clearances were made of consignments from week to week. Kernels also are selling freely both to local and interstate buyers. Brandis, 7d. to 7½d.; mixed softshells, 6d. to 6½d.; hardshells, 3½d. to 3½d.; kernels, 1s. 7d. to 1s. 7½d. per lb.

**HONEY.**—Moderate demand was experienced for honey throughout May. Unfortunately, owing to regulations regarding "foul brood," a number of sales which could have been made to Western Australia were prevented, so that stocks are now heavier than they otherwise would have been. Values are steady. Prime clear extracted, in liquid condition, 3½d. to 3½d.; best quality candied lots, 2½d. to 3½d.; second grade, 1½d. to 2d. per lb.

**BEEWAX.**—Moderate supplies; demand steady. 1s. 2d. to 1s. 2½d. per lb.

**BACON.**—The consumption of bacon was well maintained, and sales of all cuts of prime quality were effected. The factories kept the market well supplied from week to week, and values continued steady. Best local sides, 9d. to 9½d.; best local factory-cured middles, 9d. to 9½d.; large, 8½d.; local rolls, 7d. to 7½d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 1d.; local hams, 11d. to 1s.; cooked, 1s. 2d.; "Sugar Cane" brand lard, in packets, 11d.; in bulk, 10d. per lb.; local prints, 9d. per lb.

**LIVE POULTRY.**—The demand for live poultry throughout the month under review kept up better than might have been expected. As prices ruling at present are lower than they have been for some years, consumers are apparently paying more attention to poultry as against other meats, with the result that the demand is improving. The quality and condition of turkeys was, generally speaking, only poor to medium, but are now showing improvement with the growth of grass. The sales which are held every Tuesday, Thursday, and Friday are always attended by a large number of buyers. We advise consigning. Crates loaned on application. Prime roosters, 3s. 3s. to 4s. 6d.; nice-conditioned cockerels, 2s. 6d. to 3s.; fair-conditioned cockerels, 2s. to 2s. 5d.; chickens lower. Heavy-weight hens, 3s. 3d. to 4s.; medium hens, 2s. 4d. to 3s.; light hens, 1s. 8d. to 2s. 3d.; couple of pens of weedy sorts lower. Geese, 3s. 6d. to 5s.; prime young Muscovy drakes, 3s. to 4s. 6d.; Muscovy ducks, 2s. 3d. to 2s. 9d.; ordinary ducks, 1s. 8d. to 2s. 1d.; ducklings lower. Turkeys, good to prime condition, 7½d. to 9d. per lb. live weight; do., fair condition, 6d. to 7d. per lb. live weight; do., fattening sorts lower. Pigeons, 3½d. to 5d. each.

**POTATOES.**—Local, 5s. per cwt.

**ONIONS.**—Brown, 5s. per cwt.

## IMPORTS AND EXPORTS OF FRUITS, PLANTS, ETC., APRIL, 1931.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS. WOMEN'S BRANCHES.

AUBURN (Average annual rainfall, 24.08in.).

April 24th.

The meeting was held at the homestead of Mrs. L. Giles, there being six members and two visitors present. The meeting took the form of a Question Box, and household hints and some useful knowledge gained as a result. The following household hints were read by Mrs. Giles:—If turpentine, methylated spirits, or petrol is mixed with blacklead, it makes a better polish, and is easier to shine. Motor tubes cut in strips make a very good substitute for elastic, and can be used for garters or bands and legs of bloomers. It will not perish in the wash as elastic and will wear much longer. A tablespoon of vinegar mixed with a handful of salt will clean a copper perfectly in a few minutes. When making tomato sandwiches, reject the seeds; this will prevent the sandwiches from becoming too moist. If a lid is placed on a pan when frying eggs they will cook through more quickly and will not need to be turned or basted; it is better to put the pan on the side of the stove and cook slowly. When cutting up onions, do so near an open window; the breeze from the open window will blow the spray away from you and so will not make tears come into the eyes. A clear varnish on linoleum will make a good lasting polish. Clear varnish will remove marks on a stained table. Methylated spirits used with G.P. powder makes a good polish for silver. Other members also contributed useful hints. (Secretary, Miss L. Dennison.)

GLADSTONE (Average annual rainfall, 16.40in.).

April 10th.—Present: 18 members.

RECIPES.—The following recipes were supplied:—*Tea Cake for Children* (Miss Teague).—1lb. S.R. flour, ½lb. lard or dripping, ½lb. currants, ½ cup sugar, 1 egg, ½oz. ground ginger. Bake 1½ hours. *Cheap Plain Cake* (Mrs. Pritchard).—2 eggs, 1 cup sugar, ½ cup milk, 2 cups S.R. flour, ½lb. butter, vanilla to taste. Add butter last and it must be melted. Cook in moderate oven 1 hour. *Quince and Melon Jam* (Mrs. Leverington).—Take 5lbs. melon, 3lbs. quinces, 6lbs. sugar. Pare the melon and remove seeds; cut into discs; sprinkle with a few pounds of the sugar and allow to stand over night. Boil 1 hour. Pare, core, and cut up quinces. Stew for 1 hour with a few cups of juice from the boiling melon; then put the two together and add rest of sugar and boil 3 hours. *Coffee Rolls* (Mrs. R. E. Lines).—1lb. S.R. flour, pinch salt, 3ozs. butter, 2ozs. sugar, 1 egg. Beat butter and sugar to a cream; add egg, then ½ pint milk, then flour. Mix well with a wooden spoon. Roll out ½in. thick and cut with biscuit cutter and double over, and brush with milk. Cook in hot oven. *Ginger Pudding* (Mrs. Durrant).—Take 6ozs. flour, 3ozs. suet, 1 tablespoon sugar, ½ teaspoon mixed spice, ½ teaspoon C. soda, ½ cup milk, ½ teaspoon ground ginger, 2 tablespoons golden syrup. Steam 1½ hours. *Coffee Essence Cake* (Mrs. Thomas).—4ozs. butter, 4ozs. sugar, beaten together; add 2 well beaten eggs, 6ozs. S.R. flour, 1 tablespoon coffee essence. Bake in sandwich tins. *Salad Dressing to Keep* (Mrs. Humphreys).—1 tablespoon of butter, 1 tablespoon mustard, 3 eggs, 1 cup sugar, 1 cup vinegar, 1 cup milk, and salt to taste. Bring ingredients to boil and add vinegar. *Savoury Omelette* (Mrs C. H. Lines).—Chop up finely 1 large onion and cook till tender. Beat 2 eggs, add 1 tablespoon S.R. flour, 2 tablespoons milk or cream, add pepper and salt to taste. Have ready a frying pan of boiling fat; drop a tablespoon of mixture in at a time. *Jewish Cake* (Mrs. Hackworth).—½lb. butter, 1 cup sugar, 2 eggs, 1½ cups S.R. flour, ½ teaspoon ginger, ½ teaspoon cinnamon, ½ cup warm milk and in it dissolve 1 tablespoon treacle. *Orange Pudding* (Mrs. Smallacombe).—1 tablespoon butter, 2 eggs, 1 cup sugar, 2 cups S.R. flour, 1 grated orange. Steam 2 hours and serve with custard. *Three Minute Sponge* (Miss Sargent).—1 cup flour, 1 small cup sugar, break in 3 eggs, then 1 tablespoon butter, 2 tablespoons milk, and 1 teaspoon C. soda and 2 C. tartar. Put all together in a dish and beat quickly for 3 minutes and cook 20 minutes. (Secretary, Miss M. J. Sargent.)

# GOLDSBROUGH, MORT & COMPANY LTD.,

STOCK AND STATION AGENTS,

WOOL AND PRODUCE BROKERS, SHIPPING AGENTS, GENERAL IMPORTERS AND EXPORTERS, LAND, LOAN, FINANCIAL, AND INSURANCE AGENTS.

— GENERAL AGENTS IN AUSTRALIA FOR WESTERN ASSURANCE COMPANY. —

For any information regarding Fat, Store, or Stud Stock, communicate with our Stock Department for expert attention.

Distributing Agents in S.A. for—

"EDWARDS' " SHEEP DIPPING POWDER

"TONK'S" RABBIT TRAPS

"NATIONAL" CEMENT (in bags)

"RUSSELL'S" PIPING.

"COMET" WINDMILLS

"KING-LOC" STEEL DROPPERS

"W.M.L." and "TOP" BRANDS SUPERPHOSPHATES and MANURES

All Farm and Station Requirements, Fencing Wire and Standards, Cornsacks, Twine, Oils, etc., "Tattoo" Sheep Branding Oil.

"CLAN LINE AND SCOTTISH SHIRE LINE STEAMERS."

Sub-agents for—

ORIENT LINE STEAMERS, AND AUSTRALIAN AERIAL SERVICES, LIMITED.

Main Office in South Australia: 18, KING WILLIAM STREET, ADELAIDE.

Head Office: MELBOURNE.

## Metters Master "Nuoil" Double Geared Windmills, 1931 Pattern.

Manufactured in sizes from 6ft. to 14ft.

Proclaimed by experts to be the most suitable windmill for Australian requirements.

Simplified automatic governing system—no springs or weights.

Improved design, permitting easy access to all working parts.

Equipped with Replaceable and Interchangeable Bearings of Most Suitable Anti-friction Metal.

Strongest, most reliable, works with lightest breeze, and will pump more water.

Entirely manufactured in South Australia by—

## METTERS LIMITED,

NORTH TERRACE, ADELAIDE

(near Railway Station).

GOODE (Average annual rainfall, 9.82in.).

April 1st.—Present: 12 members and 13 visitors.

**COOKING DISPLAY.**—Prizes were given by certificates. Those gaining prizes were as follows:—Mrs. B. O. Klau, sponge sandwich, decorated cake, two nut loaves (light and dark), lamington squares; Miss H. Linke, home-made bread; Miss P. Linke, pound cake, collection of biscuits; Mrs. J. Kelly, cream puffs, ribbon cake; Mrs. A. E. Watson, sponge roll, scones; Miss C. Paech, collection of home-made sweets; Miss D. Tucker, sausage rolls; Miss V. Linke, yeast buns; Mrs. H. B. Linke, Belgian cake; Mrs. B. O. Klau, jam, sauce, chutney, mixed pickles, and vinegar pickles; Mrs. B. O. Klau, home-made soap. **Vegetables.**—Mrs. J. Quick, pie melon and tomatoes; Mrs. J. Kelly, apple cucumbers. **Needlework.**—Mrs. B. O. Klau, supper cloth, canvas work; Miss V. Linke, toilet set, Richelieu work, d'oyley, tray cloth; Miss M. Smith, white work, cushion, three d'oyleys; Miss H. Linke, table centre; Miss J. Smith, eyelet worked d'oyley; Mrs. A. E. Watson, child's dress; Mrs. D. Fagan, paper flowers. **Children's Needlework.** Miss D. Stasinowski, best dressed doll; Miss T. Paech, worked pinafore; Miss I. Paech, d'oyley; Miss D. Linke, worked garment. A special prize (trophy) was given by Mrs. B. O. Klau for the one who gained the most prizes for the evening; won by Mrs. Klau. A special prize (trophy) was given by Mrs. D. Fagan for the best piece of needlework; won by Miss V. Linke. A special prize (trophy) was given by Mrs. A. E. Watson for the best piece of needlework in the children's section; won by Miss D. Stasinowski. Judges—Cooking, &c., Mrs. E. M. Lutz; vegetables, Mr. W. H. Brownrigg; needlework, Miss M. Tucker.

**SALADS.**—Meeting held May 6th.—Present: Five members and three visitors.—Miss V. Linke gave a demonstration on the method of preparing a lettuce salad. Mrs. Paech also gave a demonstration of making potato salad, which can be made from old potatoes if new ones are not to be had. Method—Boil three large potatoes and slice (or mash if preferred). Fry a little bacon, cut in squares, and when both bacon and fat from the frying are cool, mix with a little vinegar to taste; add salt and pepper and sugar and cream. Pour over the potatoes. Sprinkle the top with finely chopped eschalot and a little parsley. Miss V. Linke read the following paper:—The absolute drying of the lettuce leaves is a necessity for a good salad. It is essential that salads should be served very cold. Many people like a dusting of sugar with most salads. A tomato salad is incomplete without it. Cold, white fish blends well with a potato salad. Most of the salads where oil is used may have substituted for it cream, if oil is not liked. With a French salad, the essential of success is in the slow and careful blending, without any taste of oil or vinegar, but a blend of both, and the dryness of the lettuce leaves to ensure the absorbing of the oil. French salad dressing is made as follows:—Three tablespoons of olive oil (or cream), 1 saltspoon of salt, 1 saltspoon of pepper, 1 table-spoon of vinegar. (Secretary, Mrs. A. Watson, Ceduna.)

KALANGADOO (Average annual rainfall, 32.34in.).

April 11th.—Present: 12 members.

**USES FOR OLD TELEPHONE DIRECTORIES.**—Miss Kennedy read the following paper:—“I have two directories hanging on the wall by the kitchen stove. When lighting the stove fire in the morning, a couple of leaves are torn out, and with some deal or small wood make the foundation of the fire. If the frying pan is used for cooking the breakfast, the fat is drained out and a couple of more leaves used to wipe out the pan before putting in the dishwater. A handful of pages are used for rubbing up the stove, removing any grease that has resulted from the frying. Two iron kettles used on the stove have to be lifted to the floor to be filled, and by standing them on a directory, the lino is saved from any black or scorch marks. When taking stewed fruit or boiled custard off the fire, the saucepan is stood on a directory on the table until sufficiently cool to pour into glass dishes or custard glasses. I always use a few leaves rolled into a ball and damped for cleaning the bottoms of the enamel saucepans, I just sprinkle a little Panshine on the saucepan, and after a few rubs the bottom is free from black. A directory is always used for standing the stewpan on after making jam or pickles whilst cooling before being bottled. When washing or polishing floors, I use a book for kneeling on. I have also used one when in the garden planting seedlings or pulling weeds. There are many times through the day when one wants a piece of paper, and by having one of these books close at hand, one may save much time, and you are not likely to be tearing up a paper that some of the menfolk are saving, or perhaps requiring just at the precise moment that you are destroying it.” (Secretary, Miss A. Kennedy.)

KANGARILLA.

April 16th.—Present: eight members and three visitors.

**JAM MAKING.**—The monthly meeting was held at the residence of Mrs. S. Paddick. Miss E. White read the following paper:—“The successful jam and jelly maker uses only fresh fruit of the very best quality. The fruit should be placed in an enamel or aluminium preserving pan. A deep enamel basin answers as well for small boilings.

There is no definite rule as to the amount of sugar to use, but generally speaking one can safely use  $\frac{1}{2}$  lb. (good weight) to 1 lb. fruit, though I prefer 5 lb. sugar to 6 lb. fruit, and in many instances pound for pound. Melon jam should not have pound for pound of sugar, unless oranges or lemons are added. Place on the fire and boil for about three hours, and to test if it is cooked, put a little into a saucer, stand it where it will cool in three or four minutes, look at it, and tilt the saucer and see if it has little ripples and a "skin" on it. Another test is hold up the jam spoon; if a little hangs on it in a substantial "drop" it is done. Jam boiled too long often has its color spoiled or damaged. Jam should boil briskly and requires very little stirring; use a wooden spoon. It is a good plan to put a couple of marbles on the bottom of the pan to prevent the jam from 'catching,' and stirring is not required so constantly. Bottle jam in dry glass jars, seal when cold, and store until wanted for use. 'Clag' is good for pasting down jam. Fruit that is not quite ripe is best for jelly-making. Make jelly as early in the season as possible. *Quince Jelly*.—Rub all fluff off the quinces and cut in halves to allow all jelly to be extracted from the seeds. Cover with water and boil until soft, then strain twice through a jelly bag. Put 1 lb. of sugar to 1 lb. of juice, and boil until jelly sets in a saucer. *Banana Jam*.—Slice 12 bananas, and to every pound allow  $\frac{1}{2}$  lb. sugar. Add the pulp of six oranges and two lemons and boil slowly for one hour. About  $\frac{1}{4}$  oz. of essence of pineapple improves the flavor." (Secretary, Mrs. M. Steer.)

MILLICENT (Average annual rainfall, 29.79in.).

March 20th.—Present: 10 members.

**POULTRY**.—Discussing articles read on this subject, members who had reared turkeys stated that the birds required a good deal of attention until they were well over six weeks old. Mrs. Redman stated that she had obtained good results by feeding the young birds on chopped up boiled eggs and plenty of green feed, such as thistles, lucerne, &c., as well as crushed grain. Mrs. Varcoe, who had been keeping poultry for many years, said although her birds were provided with a shed they seldom make use of it, excepting on very wet days. They preferred to roost in trees, and were always healthy and free from vermin. They were fed on wheat and had a large run where they could obtain plenty of green feed.

To remove a glass stopper out of a bottle a member was advised to hold the neck of the bottle over a flame of a candle, turning the bottle around in the candle until it became hot, when the stopper could be easily removed.

April 17th.—Present: Seven members.

Mrs. H. Altschwager read a paper giving some useful hints on gardening. She also said that to strike Daphne cuttings, it was best to cut a piece that had flowered, place it in the earth prepared for it, and put a pickle jar over it (not one with the bottom out of it, but a closed one), and keep the ground moist. Other members gave the following recipes:—*Melon Jelly*—15 lbs. melon, 12 lemons, and 3 lbs. sugar; cut up melon and lemons (include seeds and rind), cover with water, leave stand all night, boil till a pulp—do not stir—then strain through a jelly bag. Put a cup of sugar to every cup of liquor, boil until it jellies—about 30 minutes or a little longer. *Parsley Jelly*—Put some parsley in an enamel saucepan, press it down, and cover with water, boil until well cooked, then strain, put back in saucepan, adding a cup of sugar for each cup of liquor, boil until it jellies. It is nice eaten with cold meats or for flavoring white sauces. (Secretary, Mrs. H. Varcoe.)

SADDLEWORTH (Average annual rainfall, 19.60in.).

Nine members attended the meeting held at Miss Partridge's homestead on May 5th. Mrs. Coleman gave an interesting talk on her visit to Adelaide to attend the Guide and Scout Rally held during the visit of Lord and Lady Baden-Powell. Mrs. Blundell also addressed the meeting. Miss E. Campbell, of the Education Department, visited the Branch during April and spoke on the subject, "The Use of Hessian in the Home." (Secretary, Miss D. Partridge.)

WILLIAMSTOWN (Average annual rainfall, 27.71in.).

May 6th.—Present: Nine members.

**KITCHEN HINTS**.—Mrs. Hill read the following paper:—"A tin plate covered with a layer of salt takes the place of an asbestos mat and prevents jams, jellies, or stews from burning. Sprinkle a handful of salt on the stove when frying and it will absorb all the splutterings of fat and save much time in cleaning. When boiling carrots, add a little dripping; the vegetable will cook quicker and the flavor will be greatly improved. To prevent custard in large tarts soaking into the pastry and becoming soggy, sprinkle the crust with flour before pouring in the custard. To prevent jam or treacle from boiling out of a roly-poly pudding, sprinkle a few bread crumbs along the edge of the paste before rolling up. If, when making bread pudding, the buttered bread is dipped into water before being placed in the pie dish, it will not soak up so much custard.

If desiccated cocoanut is put into a jar or bottle it will not soak out as it does if left in an ordinary paper package. Vegetable marrow is much more appetising when cut into pieces and cooked in a tightly closed saucepan with a little butter, pepper, and salt. To prevent green vegetables from boiling over on the stove drop one teaspoonful of dripping into the saucepan when they begin to boil. Fried onions are much more digestible if they are boiled for a few minutes and then strained and fried in the usual way."

**HINTS FOR THE HOME.**—The following paper was read by Mrs. Rowe:—When dealing with large holes in stockings, a good plan is to get a piece of net slightly larger than the hole and tack this neatly on the wrong side of the stocking, then do the darning into the net on the right side until the opening is well covered. The work is quickly and easily carried out, and in the end will be hardly visible. When sewing with double cotton, make a knot in each end instead of knotting them together, and there will be no tangles. A little liquid ammonia added to the water in which flannels are being washed prevents them from shrinking or turning yellow. To remove a scorch-mark from delicate fabrics, make a thin paste of magnesia and water and spread it over the part, first putting a cloth underneath to avoid wetting the rest of the garment. When thoroughly dry the powder will brush off, taking every sign of scorch with it. A pinch of citric acid added when making jam or marmalade will stop it from becoming sugary. Since ants dislike the smell of sage, hang bunches of the herb wherever they are likely to be troublesome. Make a scarecrow for the garden by driving in two stakes and tying a cord across from one to the other. Suspend by string from this large corks into which long feathers have been inserted. *Beeswaxed Eggs.*—Shred 2ozs. beeswax into a cup, pour enough good olive oil over to cover, melt by standing the cup in hot water. When cold the mixture should look like wax polish. Have the eggs quite clean, grease the palms of the hands and turn each egg round in them as you would when painting a golf ball. Store the eggs in containers, such as Mintie tins, but do not put lids on the tins. Eggs done this way break like fresh ones and keep from one season to the other. *Recipe Box.*—Every housewife keeps a recipe book in the kitchen, but what about a recipe box? A small fancy biscuit tin will serve the purpose. Take off the paper, enamel the tin to match the color scheme of the kitchen, and label it "Recipes." For the interior provide some good strong envelopes—those made of thick brown paper are best—and label them "Meat," "Fish," "Soup," &c.; also one for "Household Hints." The next time you see a good recipe it will take but a second to cut it out and slip it in its particular envelope in the recipe box, and when you want something different for a pudding a search through the "Pudding" envelope will provide just the very one you need. Those recipes that have been tried and proved can be entered at leisure in the recipe book." (Secretary, Mrs. A. Cundy.)

#### WIRILLA.

January 8th.—Present: 11 members.

The meeting of January 8th was held at the residence of Mrs. Blatchford. A paper, "Gelatine," was read by Mrs. S. Schunke.

**LUNCH CAKES.**—Meeting held February 5th. Present: eight members. Miss M. Evans read the following paper:—"To make cake have everything in readiness before beginning. Mix the ingredients in a graniteware, enamelled, or earthen basin. Sift the flour before using, and if baking powder is used sift together with the flour two or three times. Use white sugar unless brown is called for. Beat the whites and yolks of eggs separately: the yolks until they cease to foam and the whites to a stiff froth. Eggs will beat to a stiffer froth if cold and beaten in a cold dish in a cool room. Use earthen or china bowls or plates to beat eggs in: a bowl if an eggbeater is employed and a plate when a fork or eggwhisk is used. First beat the butter and sugar to a cream, then add the beaten yolks of eggs, and beat and stir well; then the milk and flour, and lastly the beaten whites of eggs. Have the oven less hot for cake than for bread, but hotter for thin cake than loaf cake. A cake is baked when a clean broom straw may be passed through the thickest part without any dough adhering to it. If it is necessary to move the cake after putting it in the oven, it should be done carefully; jarring it in any way is liable to make it fall and become heavy. To prevent cake from sticking to the pan, rub the pan with butter and sprinkle with flour before turning in the batter. If raisins or dried currants are used, they should first be carefully looked over, washed, and dried, and then dusted with flour. Raisins should also be seeded. A good way to wash these fruits is to put them into a colander, set the colander in a pan of warm water for a short time until the fruit becomes plump, which will loosen the sand and grit. Then rinse by dipping the colander in and out of clean water several times, and spread the fruit on a clean cloth to dry. Raisins may easily be seeded just after being washed in this way. *Ginger Layer Cake.*—In a slightly warmed basin mix  $\frac{1}{2}$  cup treacle or golden syrup, 1 cup butter, 1 cup brown sugar, and beat well. In another basin beat 3 eggs well and add  $\frac{1}{2}$  cup milk, then add to the other mixture and beat all well together. Add  $2\frac{1}{2}$  cups flour, mixed with 1 teaspoonful each of ground ginger, cinnamon, spice, and

lastly add  $\frac{1}{2}$  teaspoonful of bicarbonate of soda dissolved in a little milk and 3 teaspoonfuls of baking powder. Divide in three, put in sandwich tins and bake in moderate oven for 20 to 30 minutes. When cold, put together with icing made as follows:—Boil  $\frac{1}{2}$  cup milk, 2 cups brown sugar, and 1 tablespoonful butter together for five minutes. Remove from fire and beat until thick. Spread between cakes and on top with a knife dipped in cold water occasionally, and decorate top of cake with pieces of preserved ginger.

*Nut Loaf.*—Sift 1 teaspoonful cream of tartar and  $\frac{1}{2}$  teaspoonful carbonate soda with 2 cups flour into mixing bowl, add  $\frac{1}{2}$  cup sugar, and almonds, raisins, and dates as desired. Beat separately 2 eggs, and to them add 1 tablespoonful golden syrup and  $\frac{1}{2}$  cup milk, add the flour, and mix well. Put in well-greased tins with lids loosely on, half fill each tin, and bake one hour.

*Lunch Cakes—Buns.*—Three cups self-raising flour,  $\frac{1}{2}$  cup dripping or butter,  $\frac{1}{2}$  cup sugar, 2 eggs, a few drops of essence of lemon, and milk. Beat butter and sugar to a cream, add eggs well beaten, and then flour and sultanas or currants as desired, and enough milk to make a stiff dough. Roll in balls and dip in sugar, and bake in moderate oven.

*Sultana Cake.*—Three cups flour, 1 cup butter, 1 cup sugar, 1 cup sultanas, 4 eggs, and  $\frac{1}{2}$  cup milk. Beat butter and sugar to a cream, add eggs well beaten, then add sultanas, milk, and flour and beat well. Bake in moderate oven for one hour."

**BISCUIT MAKING.**—Meeting held April 2nd. Recipes were supplied by Mrs. Jones. Mrs. Schunke read the following paper:—"There are many recipes which anyone can follow, and there is such a variety of colorings and flavoring essences available that it is possible to suit all tastes. Biscuits can be made very attractive by different icings and fillings, and by having a number of fancy cutters. For most biscuits the butter is rubbed into the flour and the eggs well beaten with the sugar and mixed into a soft dough, rolled very thin, and cut into shapes. Most biscuits will keep for weeks crisp and nice if kept in an airtight tin. The following are three easy recipes:—*Champagne Biscuits.*—Half pound butter, 1 cup sugar, 1 egg, 2 cups flour, 1 teaspoonful cream of tartar,  $\frac{1}{2}$  teaspoonful carbonate soda, and milk to mix. Rub the butter into the flour and add egg and sugar well beaten together, enough milk (about 3 tablespoonfuls) to mix a stiff paste, add essence vanilla, roll thin, and bake quickly. *Rosella Biscuits.*—Two cups self-raising flour,  $\frac{1}{2}$  cup cornflour,  $\frac{1}{2}$  cup sugar,  $\frac{1}{2}$  lb. butter, 2 eggs, saving the white of one, and a little milk; mix ingredients well. Roll out thin and spread with white of egg beaten stiff, and add icing sugar to make a stiff paste. Sprinkle with cocoanut or chopped nuts. Cut in strips and bake. *Shortbread Creams.*—One pound flour, 2ozs. sugar,  $\frac{1}{2}$  lb. butter; beat butter to a cream, add sugar and flour sifted. Work it into a ball and roll out, cut in shapes, and bake in a moderate oven half an hour. Put two biscuits together with a filling comprised of 1 tablespoonful butter, 3 of icing sugar, and flavoring essence. These biscuits are also nice with half an almond put in the centre of each before cooking." (Secretary, Miss W. R. Jones.)

## AN EXHIBITION OF HOME CRAFTS AT GLADSTONE.

An instructive and practical feature of the work of the Women's Branch of the Agricultural Bureau at Gladstone is the encouragement of domestic crafts. An exhibition of work accomplished in the homes of members was inaugurated in 1930, and the second display was held on Wednesday, May 13th, in the Memorial Hall of the Gladstone Institute, when a large number of visitors, including members of neighboring Women's Branches at Nelshaby and Gladstone, inspected the work done during the year.

**Charles Whiting & Chambers Ltd.**  
13, PITT STREET, ADELAIDE.

The exhibits were divided into three classes, which were open for competition:—Jams (made from dried apricots), spongecake, and a collection of articles made in the home. The entries for the latter class were not restricted to members of the Women's Branch, as the conditions provided that the collection must be made in the homes of Bureau members. Consequently, there were exhibits of such articles as furniture, made by members of the Men's Branch, and amongst the entries visitors were particularly interested in the work of Mr. T. Hackworth, who displayed a tea wagon, rug box, afternoon tea table, fire kerb, and a settee. The only materials purchased for the manufacture of the settee were the moquette and springs, the frame being made principally from a discarded harvester.

Including a special class for Christmas cake, which was judged in 1930, there were 24 competitors, some of whom entered as many as 150 articles in the home collection class. This class consisted of art needlework, dressmaking, crocheting, stencilling, knitting, painting, newinlach work, tatting, woodwork, cooking, jams, preserves, furniture, and upholstering, &c.

The attractive display of art needlework of all exhibitors was a distinguishing feature of the competition, as well as the excellent exhibits of dressmaking of various kinds, painting, cooking, and sweets entered by Mrs. R. E. Lines, who gained the highest aggregate for all classes, with 178 points out of a possible 200. Other competitors for the aggregate, in order of merit, were Mrs. T. Hackworth (170 points), Miss Sargent, Mrs. G. Smallacombe, and Miss Brown.

The competition for jams made from dried apricots (judged by Mrs. Smallacombe and Miss Jeffrey) was won by Miss M. J. Sargent, with Mrs. Hackworth second. Mrs. G. Smallacombe secured the first award for sponge cake (judged by Mesdames E. L. Orchard and H. J. Richardson), and Mrs. R. E. Lines was placed second. In the home collection class (judged by Mesdames L. Clarke and Cummings), Mrs. R. E. Lines was awarded first place, followed by Mrs. Hackworth, Miss Sargent, Mrs. Smallacombe, and Miss Brown.

Mrs. Gravestock, Miss Sargent, and Mrs. Smallacombe were placed in this order for the Christmas cake, which was judged in December last.

Prior to the general inspection of exhibits by visitors, Mrs. F. C. Spotswood, in the absence of the President (Mrs. M. A. Schmidt), presided over the meeting, and explained the objects of the exhibition, which were primarily to encourage country women to provide their homes with essential and decorative articles made by their own handiwork, and she was convinced that the large attendance of interested visitors would prove an incentive to the Gladstone Branch to continue the competitions, which were so well founded last year. She announced that the trophies won would be presented at the annual meeting of the Men's Branch, to be held later in the season.

The Secretary (Miss M. J. Sargent) was complimented on the manner in which she had carried out the details of the competition, and on the excellent work she had done for the Branch.

The visitors listened with interest to the remarks of the judges, after which addresses on the work of the Bureau were given by Messrs. H. C. Pritchard (General Secretary) and E. L. Orchard (District Agricultural Instructor).

The following ladies contributed to a musical programme before afternoon tea, which was served by members of the Branch:—Mesdames Symonds, Clarke, Glen, Osmon, and Misses Jeffrey, Lines, and Deeble.

## SOUTH-EAST DISTRICT.

WOLSELEY (Average annual rainfall, 18.30in.).

The September meeting was attended by 27 members. Mr. R. A. Grosser read a paper concerning the merits of winter and summer fallow.

A "Question Box" meeting on November 11th was attended by 22 members. In reply to the question "Does it damage fallow to work with the disc if fallow is badly infested with thistle?" Mr. Snod thought the disc preferable to leaving the thistles. Mr. Oborn had used the disc on part of the crop, and had not found it detrimental to the growth of wheat. "Does it pay to breed draught horses on the farm?" Mr. H. K. Ridgway did not think it advisable on a small farm. It would be better to buy two or three year old colts and crop the land. Mr. W. Butler thought it better to breed than to pay £30 for a horse. "Which is a good wheat to grow on stubble land?" Several members thought Waratah a good wheat. Mr. C. Ridgway had tried Major, but without success. Mr. Oborn considered Dollar was the best he had tried. (Secretary, Mr. E. Sharrad.)

January 12th.—Present: 15 members.

FARM SIDE LINES.—The following paper was contributed by Mr. W. Butler:—"All people interested in the welfare of our State will agree that wheat and wool are the principal sources from which our wealth is obtained, and in this paper on 'side lines' I am not justified in putting either of these products down as side lines. It must be admitted that without sheep on the farm—particularly the fallows—our district would not grow nearly so much wheat, so it can scarcely be reckoned as merely a side line. As this paper deals with side lines which can be made to assist the farmer to balance his budget, I think the most important side line is dairying and the rearing of young cattle. Every farmer should keep cows. With care and good management the cows should not be all in full milk at the same time, or there will be a shortage of milk and butter, perhaps just when it is most needed. If a farmer has a family able to manage a few extra cows, well and good, as it would be far better for him to do so than to think of any of his family seeking employment away from home. Separator butter is a commodity which finds a ready sale. Another side line well worth trying is the keeping of a good breed of swine. With two or three good sows one should be able to utilise the separator milk. Young pigs thrive on that kind of diet, if a little pollard or crushed wheat be added. A small paddock of clover or lucerne would prove beneficial. A supply of charcoal is a good thing to have for the pigs to eat; it helps to keep them healthy. If young pigs are not in demand, the farmer can kill and cure the pork or bacon, and it will assist in keeping down expenses. Another side line I strongly advise is poultry, especially if there are girls in the home. For laying hens I prefer White Leghorns. Egg production pays better than breeding, first because of our distance from market, and again, a young cockerel will eat a bushel or more of wheat before it is fit for market. With corn at 2s. 3d. per bushel and a bird in the market at 5s., it would be a consideration. We are frequently told that a certain breed of fowls are best because they are winter layers. I have been interested in fowls for many years, and have understood that the time of the year in which hens lay is determined by the date of hatching, and if a pullet begins to lay when nine months old—as many folk aver—it should not be a very difficult task to prove when or at what time of the year is the best for hatching. Eggs being such a valuable food and so easily and quickly cooked, makes them a line well worth venturing on, but do not expect a fortune all at once. Many people keep their hens too long, i.e., until too old to be profitable. I remember reading some years ago a report on this important subject, which stated that 12 pullets one year old would lay as many eggs in a year as 17 two-year-old hens, and as many as 24 three-year-old hens, so you should brand or mark them. Recently eggs were quoted at 5½d., to 1s. 2d. for Red Combs. The eggs which brought 1s. 2d. were guaranteed infertile. If this makes so great a difference, why keep mixed sexes running together? Would it not be better to house the best hens with a pedigree male bird, and thus obtain hens of the best laying strains. Lastly, a side line worth writing about is a good vegetable garden, as every good housewife delights in fresh vegetables, knowing they cost but little." (Secretary, Mr. E. Sharrad.)

February 9th.—Present: 24 members.

SHEEP OR WHEAT FOR THE TATIARA DISTRICT.—Mr. Butler read the following paper:—"I have divided my paper into three parts, and arguments and figures are based on a farm of 500 acres: I., Sheep only; II., wheat only; III., wheat and sheep. *Sheep Only.*—I estimate one could carry 350 ewes; these would drop 80 per cent. lambs; 280 lambs from 350 ewes, wool shorn 8lb. per head at 9d., 6s. = £105. I would sell the lambs off shears at, say, 6s., and with the wool = £95. Total income £200. I estimate cost of

shearing, £30; dipping, crutching, woolpacks, &c., £10; leaving a credit of £160. *Wheat Only*.—Seeing that various experts have estimated that wheat costs 4s. a bushel to grow, that is, wages, &c., I will now only deal with a farmer who does his own team work and makes no allowance for his wages, but profits, if any, are his livelihood. I am of opinion that a man can put in 180 acres wheat each year; estimating this at 25bush. to the acre at 2s. per bushel, £450; roughly, expenses would be:—Super, £50; cornsacks, £55; wear and tear, depreciation on machinery, £50; insurance, £5; seed, £25; various small items, £50; total expenses, £235; leaving £215 profit. As regards balance of holding, I would let the grass on this for sheep for, say, £50, which would bring profit to £265. *Sheep Combined with Wheat*.—Estimating that I put 150 acres under wheat, 150 under fallow, the remaining 200 would be grazed by sheep, leaving 50 acres sown for oats, would leave 150 acres. On this I estimate 200 ewes could be kept. These would rear 150 lambs. I estimate wool from sheep and lambs at £65, lambs sold off shears £45—total £110; expenses in connection therewith, £10; credit of £100. With balance from wheat, which amounts to five-sixths of previous estimate, leaves an estimated profit of £180. Total receipts from sheep and wheat, £280. Profit as under: Sheep only, £160; wheat only, less £93—£265—£172; sheep and wheat, less £77—£280—£203. These figures are open to argument. Parts of many farms are of no use for wheat growing, being too wet, &c., whilst, on the other hand, we have good paddocks that it would be against all reason not to grow wheat on them. Some parts of the district are more suitable for wheat-growing, being close to stations and receiving yards, whilst others situated 20 miles out find carting too expensive. These figures are given as farmers who own farms. We find in the district there are many men working farms on shares. But for this system many at the present time would probably be on the dole. If we take two-thirds or one-half of my figures you do not give them much profit; the same also applies to the owner. You do not want too many eggs in the one basket, and it is sound business to combine both sheep and wheat. This is a good district, and droughts are few, so that we should grow more wheat. When we travel the district we see very little fallow compared with grass country.” (Secretary, Mr. E. Sharrad.)

## UPPER-NORTH DISTRICT.

### (PETERBOROUGH AND NORTHWARD.)

BLACK ROCK (Average annual rainfall, 12.50in.).

March 3rd.—Present: Six members.

**MAKING FARM LIFE ATTRACTIVE.**—Mr. G. Clarke read the following paper:—"When the work of the day is finished have a shower and change into fresh clothes. Punctuality with regard to meals and work will tend to help you through your tasks. A wireless set is a valuable asset to the man on the land; from it he receives valuable information, market reports, sporting results, and music. Outdoor recreation, such as tennis, football, golf, cricket, &c., should not be overlooked. It should be the ambition of every young man to play some sport. This takes the mind off the work of every day and gives one a brighter outlook on life." (Secretary, Mr. Kitto.)

MORCHARD (Average annual rainfall, 13.50in.).

March 6th.—Present: 10 members.

**ODD JOBS.**—Mr. H. Kupke read the following paper:—"First, I suggest attention should be given to tidying up around the house. If doors are squeaking give them a drop of oil. Mend guttering and attend to the paths before winter. Look at the roofs of sheds. A few sheets perhaps want nailing down securely. The water supply for domestic purposes should have attention. Clean all tanks and piping. Fix up drains and channels to the dam and tanks. Attend to the stables, repair stalls, feeders, and

yards, and see that the cow shed and yards are ready for winter weather. Crossings in small creeks can be fixed up, say, with a load or two of stone, or any washouts repaired. Firewood should be carted and sawn up as early as possible. Once field work has started and no wood sawn, it often means that there is so much extra to do cutting firewood before breakfast. See that harness is in good repair, and have all leather dressed with oil. I prefer black harness oil. See that all burrs and thistles are destroyed. Before seeding go over the combine and have all necessary repairs effected. After seeding remove any large stones and stumps. Perhaps gates have got out of repair, or wires tangled and broken. These must be mended without delay. A few wires in the crop paddocks may be broken, or gutters washed out. If this is seen to it will prevent stock getting at the crops. On wet and cold days in the repair shop all classes of repair work can be undertaken—mending chains, swingle-trees, chain hooks, and sharpening crowbars, harrows, and steel shares, &c. To do this efficiently, have a repair notebook and enter all fittings wanted and necessary adjustments. Make a cocky chaff scoop and two or three hen and chicken coops. As spring approaches, paint any wood-work on wagons, hay frames, gates and doors, and any wood that wants protection from rain and sun." Mr. A. Lang thought paint too expensive for gates. He favored coal tar. Mr. Kupke said that for painting gates coal tar and cement mixed together was good, also linseed oil. Charcoal would stop rot in posts; and yellow ochre and coal tar made a green paint. Mr. R. McCallum read a paper entitled "Cheapest Method of Gathering a Crop in this District." (Secretary, Mr. A. McCallum.)

March 27th.—Present: nine members.

Mr. B. Koch read a paper, "Sport on the Farm." Many people hold the opinion that the farm cannot be worked properly if sport is encouraged. Farmers work long hours, but sometimes do not give any encouragement to young people to take part in recreation and sport. Life on the farm is often made a drudgery by working too long at one job. The work becomes dull and monotonous, and tends to make the young people long for the city, where more sport is available. It may be said that some of the wealthiest farmers never thought of playing games but only of work and money, but that does not apply to the present day. The young people that do not join in sport in the present day are missing a most enjoyable phase of social life. It is on the playing ground that they meet the best young people. Not only do we play against them, but we meet others with whom we can discuss farm topics, forget our own ills for the time, and make farm life brighter. All young people should join the Agricultural Bureau; they will gain much useful information. Young men and women who wish to be suc-

C. F. ANDERSON, Poultry Expert.

cessful in life must play sporting games. Sport is a character builder; it teaches us to give and take and play the game. A half a day off between the busy months goes a long way towards making farm life happy. Sport is sometimes overdone, but people that allow this to happen are not the best farmers." (Secretary, Mr. A. McCallum.)

**WEPOWIE** (Average annual rainfall, 13in. to 14in.).

April 20th.—Present: 10 members.

**ECONOMY ON THE FARM.**—Criticising a paper on this subject, which had been written by Mr. H. Roocke, Mr. W. Gregurke said that increased production was one of the few ways of minimising overhead expenses at the present time, and that travelling was a profitable investment, because knowledge gained often resulted in a large saving of time and expense. Mr. J. F. Burns thought super and cornsacks were the farmers' bugbears, they had no control over either, and through those channels many a farmer had met his present unfinancial position. Mr. J. Crocker thought the farmer had very little control over the spending of his money because of the fixed prices for necessary goods, such as super, cornsacks, machinery, and high interest rates, there was only a very scanty margin left for the farmer to use at his own free will. The living standard of the average farm household left very little room, if any, for reducing expenses. Mr. Crocker also favored travelling as a very useful side line to effective economy, but at present he thought too many holiday makers favored the city. A trip to another State or to some farming district of our own State or the Territory were ideal places for farmers and farm hands in which to spend a holiday. Mr. T. Orrock stated that economising now, when everything was at its lowest, was very hard to do, but when good seasons prevailed too little care was exercised in keeping down overhead expenses. New machinery was bought when a few repairs to an old machine would have made it workable for a further period of years. Light working of the soil was one way of reducing production costs. Mr. E. Roocke considered that land in many instances was worked when not at all warranted, especially in dry seasons. In practically every instance where fallow had been worked frequently the lowest returns have been received, thus increasing the cost of production, whereas on the other hand if fallowed to a depth of 1½ in. to 2 in. the soil needed very little working to keep it in quite a good state, unless, of course, heavy rains caused it to firm too much or weeds predominated, then working was essential, otherwise if harrowed once or twice it made a very fine seed bed at the minimum of expense, so essential at the present depressed period. (Secretary, Mr. E. Roocke.)

**MIDDLE-NORTH DISTRICT.**

**(PETERBOROUGH TO FARRELL'S FLAT.)**

**BLYTH** (Average annual rainfall, 16.86in.).

October 3rd.—Present: 21 members and visitors.

**THE TEETH OF THE HORSE.**—Mr. A. Webber read the following paper:—"The teeth of the horse are a very important part of his constitution. It is very important to see that the young horse casts his front or milk teeth; if not, they should be extracted, for they not only cause injury to the permanent teeth trying to come through, but if left will 'set in.' A horse at 2½ years old should have his middle teeth, top and bottom permanent, at 3½ years he should have four top and bottom permanent, and at 4½ years the six top and bottom, and in the case of a stallion or gelding he should have two tusks, commonly called bridle teeth. At 4 years the animal starts to shed his molars or grinders, and it is rather a bad time for a horse. The doing up of horses' teeth is not pleasant work, but all horses should have their teeth examined and attended to if necessary. This should be done, say, at 3 years old. Prevention is better than cure, and a little attention at that time may save years of suffering and make the animal much more useful and valuable to his owner. Farmers are inclined to wait until they see a horse slobbering or unable to eat at all, and then they expect the vet to

put the teeth in order and the horse to get fat in a week or two. The cost of having them attended to is very small considering the benefit to the horse and through him to the owner. A large number of the internal troubles of horses are caused through bad teeth. Defective teeth have an important bearing on the health of a horse." Mr. E. Molineux gave a report of the work of the Project Club at the local school. (Secretary, Mr. L. Mugge.)

#### EVERARD EAST.

April 8th.—Present: 10 members.

**PIGS FOR MARKET.**—Mr. A. Higgs read a paper, "Which is the Best Pig to Breed for Market?" He favored the Berkshire or Berkshire Mid-York cross, and said the sow should have a fair allowance of skim milk while rearing the pigs; failing milk, sloppy pollard should be used. When fattening, it was best to feed grain dry, because it made harder meat.

Mr. H. Wilkin also read a paper, "Which is the Best Wheat for Hay?" He favored King's Early, White Tuscan, Bluey, and Waratah, and said horses did not like Nabawa, only eating the heads. Mr. E. Colton said horses would not eat King's Early, and even cows did not seem to like the chaff. Mr. C. Hughes preferred Early Gluyas; it was very heavy and carried a good grain with a green straw. After a good discussion, members agreed that the apparent dislike of the horses for the hay was most likely due to red rust, most wheats being rusty this year. (Secretary, Mr. F. Hughes, Blyth.)

#### MURRAYTOWN.

April 15th.—Present: seven members.

**OTHER MEANS OF MAKING MONEY ON THE FARM BESIDES WHEAT GROWING.**—Mr. B. Starr contributed the following paper:—"Primary producers must find other means of adding to their income and not depend wholly on wheat, for it is more than likely that seasons will be better from now on for at least a few years. I suggest that fodders and grasses such as lucerne, Sudan grass, rye grass, and Subterranean clover and Cape barley be grown to provide more green feed for cows, pigs, and poultry. This will also allow extra green feed for the working horses and save feeding all hay. If this is done and well-bred stock kept, it will be possible to augment the income from wheat and sheep. Further, it will be possible to get a better price for some of the grain by sending it to market on the hoof." (Secretary, Mr. E. Pitman.)

A meeting was held on March 6th. The Hon. Secretary (Mr. E. Pitman) read a paper, "Wool Growing in Australia."

#### NARRIDY (Average annual rainfall, 15.93in.).

Meeting held November 18th. Present: 12 members. Reports of the delegates to the Annual Congress were received and discussed. (Secretary, Mr. H. Cox.)

### LOWER-NORTH DISTRICT.

#### (ADELAIDE TO FARRELL'S FLAT.)

##### LIGHT'S PASS.

March 2nd.—Present: 36 members and visitors.

**SHALLOW CULTIVATION.**—Mr. T. Roenfeldt, in the course of a paper on this subject, first gave a description of the action of moisture in the soil and the function of soil bacteria. The paper then read as follows:—"The system we have adopted for the last 20 years, and the one which has given the best returns in this district, is to fallow in June or early July (weather permitting), the land not to be over cultivated. Ploughing from 2½ in. to 3½ in. in depth (never over 4 in.), which can only be accomplished by cutting a furrow not more than 8 in., much better by cutting 6 in. The land to lay as open and rough as you can get it over the rest of the winter, and then harrowed down

by the end of August. The first cultivation after harrowing should be a thorough spring toothing to the ploughing depth, in order to bring the clods to the surface, and so sift the fine soil to the bottom to form a compacted layer. Early ploughing allows this initial cultivation to take place at a more suitable time; it should at least always be done by the end of September before the advent of hot, dry weather, otherwise the activity of your soil bacteria is checked. Subsequent cultivations should be shallower every time, and done with the object of stirring the mulch soil only, keeping it in a loose condition and weed free. It is in these workings that wheat growers chiefly err. Insufficient attention is given to regulating the implements to work uniformly at the correct depth, particularly approaching seeding time, and not infrequently a loose, open soil is the result at the time. With such a condition root growth is checked, normal growth cannot take place, and being in a weakened condition, the plants are more susceptible to attack by parasitic disease, such as takeall, haydie, &c. Never work the ground when it is too wet, or the mulch will set down very hard, and under no condition work the fallow dry after November. Always run over the fallow immediately after rain that causes a crust to form, even if it is only with heavy stump jump harrows. The general inference is that under our district conditions relatively shallow tillage is more profitable than deep tillage for wheat growing, because in the event of floods or a very wet year the soil will wash away as far as it has been cultivated, and the ground will not become waterlogged and sodden, and all the bacteria checked or destroyed by cold and over-moisture as would happen when too deeply tilled. Over an average number of years my experience has convinced me that shallow tillage is by far the most profitable." Mr. J. Tschärke read a paper on "Deep Ploughing." (Secretary, Mr. C. Verrall.)

March 30th.—Present: 28 members.

MANURIAL EXPERIMENTS WITH GRAPES.—Mr. A. J. Chapman supplied the following report:—*Gypsum Experimental Plots*.—The yields from the various plots for 1931 were as follows:—Plot No. 1: 1 ton of gypsum per acre, 1926, yielded 615lbs. Plot No. 2: Check plot, no manure, 500lbs. Plot No. 3: 1 ton gypsum per acre, 1926, and 3cwt. of super annually, 730lbs. Plot No. 4: Received 3cwt. of super per acre since 1926, yielded 700lbs. From these figures it will be seen that the plots receiving super have shown a considerable improvement over the check plot, sufficient to more than cover the cost of super used; in fact, for the first time since the experiment commenced the supered plot has been almost as profitable as the No. 1, which received gypsum only.

| Means . . . . .                        | 612½           | 495½           | 649½           | 569½           |
|                                        | £ s. d.        | £ s. d.        | £ s. d.        | £ s. d.        |
| Total cost per acre . . . . .          | 1 10 0         | —              | 5 5 0          | 3 15 0         |
| Value of increased yield at £6 per ton | 4 13 8         | —              | 6 3 9          | 2 16 7         |
|                                        |                |                |                | Loss           |
| Profit over cost of manure . . . . .   | 3 3 8          | —              | 0 18 9         | 0 18 5         |

It will thus be seen that the plot which received gypsum only has been easily the most profitable over the five-year period, followed by No. 3, which received super in addition to gypsum; No. 4 has shown a loss of 18s. 5d. over the period. The general appearance of the plots at the present time shows that No. 3 is in much better heart than any of the others, the vines having become much more robust in appearance in the five years. This plot is certainly in a much better condition to bear crops in the future than any of the others. Plot No. 1, gypsum only, is in fairly good condition, but the general appearance of the vines is not so outstanding as two years ago. Super only, No. 4, certainly looks better than the check plot, but the vines have not the same healthy appearance as where gypsum was applied. In spite of the fact that the gypsum only plot was the most profitable, I prefer to use a moderate dressing of super as well as gypsum on this class of soil, as I am convinced that it would be the most profitable eventually."

Mr. F. W. Boehm gave the following paper, "Season's Report on Apricots":—"After last year's good crop and dry season the trees were looking good, so far as buds were concerned, in June and in early July in the Light's Pass district. Later in July and early in August buds were not looking healthy, probably the dry spell in June and early July made the buds move, and when rain came the buds were checked

and caused them to look unhealthy. I sprayed earlier than usual on account of buds not looking so healthy. Towards flowering time buds seemed to have improved a little, especially on young trees, which bloomed well and the setting was good. Old trees did not bloom so well, and the setting was patchy. Trees were pruned in July and finished the first week in August. Favorable weather conditions prevailed during the first half of September, and ploughing was continued right through that month. On October 5th a shower of hailstones passed through the district, but caused only slight damage. Nice rain followed, which benefited the apricots and the gardens generally. Apricots had a healthy and clean appearance, but were uneven in size, and some of the fruit started to drop. Not much rain followed during the next two months, yet the apricots filled out nicely, but only a fair crop was harvested. £6 was offered by the buyers at the factory door—only about half of the production cost. It is to be hoped that the newly formed Fruitgrowers' Association will be able to bring about a better price next year."

**DUCHESS PEARS.**—Mr. C. B. Robin reported as follows:—"Flowering patchy, and weak, with a very light setting. Owing to the light crop the fruit was of good size, notwithstanding the dry season. Shipments of Duchess on a fairly large scale were made to relieve the local market. The last shipment realised satisfactory prices—12s. to 14s. per three-quarter case; half cases 5s. to 7s. each. Final returns not yet to hand, but growers expect to realise 3s. to 5s. per case, if expenses are not too heavy. The Duchess will always prove a risky pear for export, however carefully handled, owing to its early ripening, but at the present time growers have practically no other outlet, and when the crop is normal, if nothing is done, hundreds of thousands of cases will again be left to rot, as was the case last year. Very few pears were sold for canning, and the price paid was only £5 per ton, which is the bare cost of production in a normal year. *Fresh Fruit.*—Owing to the scarcity of apples, pears have been selling at quite a satisfactory price, but, of course, this would not occur in a normal season. There is something radically wrong when factories will not buy our fruit for canning on the grounds that they cannot compete. If the other end of the business was handled properly the demand for our pears would quickly overhaul the supply. Of the late varieties of pears there is a very light crop, only Umlauf and Kieffer being 'on' this season, and, owing to the shortage of apples, a satisfactory price is being realised—from 6s. to 8s. per case. From last year's export returns it seems that in our late pears we have concentrated too much on the Glou Moreau, as the extra 2s. to 3s. in London brought by the better varieties makes all the difference to the profit or loss incurred by the exporter." (Secretary, Mr. C. Verrall.)

## DAIRY CATTLE IMPROVEMENT ACT, 1921.

# SALE OF PUREBRED BULLS

Dairymen are again reminded that on and after July 1st, 1931, no bull will be accepted for sale under the Government Subsidy Conditions unless its dam has qualified under the present butterfat standards. It is suggested, therefore, that persons who desire to sell, under subsidy, bulls which are eligible only under the old standards, should effect the sales at once.

February 26th.—Present: six members.

**SIDE LINES.**—Discussing a paper on this subject which was read by Mr. K. Young, Mr. F. Nicholls said that when one had to employ labor to look after a sufficient number of side lines to be worth while, it would not pay, but that over a period of years wheat-growing would prove to be the mainstay. Mr. C. Nicholls was not in favor of side lines to any great extent, but thought everybody should produce enough for their own use. The danger in everybody doing the same thing would cause a less return. In their district wheat was the main object in farming. Mr. E. Hamdorf said side lines were paying better now than at other times, but the expense in getting herds together at present was not warranted, as the income in future would not be assured. Mr. W. Hamdorf said much depended on the size of the farm whether a man could manage side lines successfully. They were an asset, but they must stick to wheat if they had sufficient land. It paid to have side lines on a farm. Mr. N. Robinson said side lines were considered as pocket money years ago, but at present they were very necessary for the use of the household of a farm. The President presented to Mr. A. F. Herbert a Life Member's Certificate of the Agricultural Bureau of South Australia. (Secretary, Mr. N. Robinson.)

April 2nd.—Present: Seven members.

**UNIMPROVED LAND VALUES OF A WHEAT FARM.**—Mr. C. Nicholls read the following paper:—"To arrive at the unimproved value of land it is necessary to ascertain what that land would be worth to a man with money to invest if it was still in its natural state. There are many things that go to control that value. It is necessary to take into consideration the cost of clearing and general costs of working, and the producing capacity and advantages in social services, such as schools, railways, water reticulation, and postal communications. For the purpose of arriving at the unimproved value of land on the average farm in this district, I am taking a holding of 1,000 acres and assuming that it was originally covered with fairly heavy mallee timber. Before such a farm could be brought to its maximum earning capacity a big outlay of capital is necessary, and would be required to be spent on the following items:—Clearing 1,000 acres at £3 per acre, £3,000. Buildings—House and man's room, £750; implement shed, £80; stables, chaff shed, and engine room, £120; barn and shearing shed, £60; smithy and motor shed, £30—£1,040. 900 chains of fencing, with necessary gates, troughing, and sheep yards, £900; Working plant and stock—Implements, £995; 15 horses at £25 per head, £375; 300 sheep at 13s. 4d. per head, £200—£1,570. Total capital, £6,510. Having spent approximately £6 10s. per acre on the farm, it should be capable of growing 20bush. of wheat per acre on 350 acres of well-worked fallow, besides growing sufficient hay and feed to carry the necessary stock. The only basis on which it is possible to work out the unimproved value is to find out what annual profit can be got from such a farm. The annual expenditure is as follows:—6 per cent. interest on capital outlay, £390. 2 per cent. depreciation on buildings and fences, £39. 5 per cent. depreciation on implements and harness, £40. 10 per cent. depreciation on horses, £38 10s. Council and water rates, £35. 23 tons super, £120. 2,180 cornsacks (at 10s. dozen), £90. Twine, oil, grease, fillings, &c., £30. Travelling expenses, £5; telephone, £5; and insurance, £15—£25. General repairs, £20. Wages for self and man, £300. Total annual expenditure, £1,127 10s. Annual receipts—2,180 bags of wheat at 3s. 6d. per bushel, £1,144 10s. Wool from 300 sheep (7s. per head), £105. New profit from sale 200 fat sheep (4s. per head), £40. Total annual receipts, £1,289 10s. From this amount we deduct £1,127 10s. for expenses, leaving profit of £162. By capitalising this amount with interest at 6 per cent. we find that the total unimproved value of the 1,000 acres would be £2,700, or £2 14s. per acre. Discussion.—Members considered it a very fair statement for a normal year, although a 20bush. average seemed high at present, considering the last few years. It was an opportune paper, considering the controversy on the subject at present. The profit was considered small, taking into account the amount of capital involved. (Secretary, Mr. N. Robinson.)

## RIVERTON (Average annual rainfall, 20.81in.).

March 9th.—Present: nine members.

**CROP COMPETITIONS.**—Mr. J. E. Kelly read a paper on "Crop Competitions," in which he suggested that there should be three sections: (1) for farms of from 300 to 500 acres on the basis of an entry of 25 acres in one paddock and one variety of wheat; (2) for farms of from 500 to 600 acres on the basis of an entry of 50 acres in one paddock and of one variety; and (3) for farms of 900 acres upwards on the basis of 100 acres in one paddock and of one variety. By this arrangement he considered that the competitors would be on the same footing in each section, and that it would stimulate interest among the smaller growers. He thought that the competitions were mainly won by farmers with larger holdings, and other competitors could not do themselves justice in a competition when they were obliged to enter against the bigger landowners. Taking, also, the varying nature of soils into consideration, it was impossible for a farmer whose

farm consisted of from 70 to 80 per cent. limestone or loamy soil to compete with the farmer whose land was of heavy black or Bay of Biscay land. He claimed that the farmer who could produce an average of 20bush. to the acre on limestone country was growing a far better crop, relatively, than the farmer who grew 30bush. to 35bush. on black or Bay of Biscay soil. Both crops were judged on the same footing, and no allowance was given for the class of country. He realised, however, that this point would be difficult to overcome, but there was, nevertheless, an inequality. He thought that the method of awarding points for yield should be adjusted. It was often difficult on account of various circumstances for anyone to give an accurate estimation of yields, and he referred to cases where estimation of yields were very different to actual yields. He maintained that the winning crop in a competition should be the crop which returned the greatest profit per acre. In discussing the paper, Mr. F. W. Coleman said that a small farmer would have a better crop—by working his land more—than a farmer on a larger holding. Mr. J. McInerney (Chairman of the Midlands Competitions) said that land worked for three years previous to cropping would give the best yield. The weighing of yields would not work advantageously, and it was necessary, therefore, to keep to the system of awarding points on apparent yield. He was pleased that Mr. Coleman had won the three-year Competition on the average number of points and that the trophy came so close to the Riverton district. (Secretary, Mr. O. Longbottom.)

#### ROSEDALE.

March 3rd.—Present: 14 members.

**CALF REARING.**—Mr. G. Sincok, in reading a paper on this subject, first emphasised the importance of obtaining the services of the best bull that finances would permit. He also suggested that if funds would not allow the farmer to purchase a bull for the sole use of his own herd, he should discuss the matter with a neighbor and endeavor to buy a sire on a co-operative basis. Prior to calving, the cow should be kept in good condition to maintain bodily health, produce milk, and develop the calf. As calving approaches it will be noticed that the cow's milk supply falls away. There is nothing to be gained by trying to keep her in full profit; let her go off a little at a time until seven and a half months, when there will only be about seven weeks to wait for her

## PLANT MORE TREES

to freshen. If the cow is not on good feed, see that she is stall fed with bran, crushed oats, linseed, and good, green chaff. It is necessary when she is finishing off the calf that she does not have to go hungry. I feed about one week after the cow dries off until she comes in; she will then be in good order for the year's work, and produce a calf that will be a pleasure to rear. It is not advisable to heavily feed a fat cow on oats and linseed, but she should have plenty of chaff and grass. When the calf is born, it should have the first milk from the mother for the first three or four milkings, after which it can be taken away from the mother. Keep the calf out of sight of the mother and in 12 hours it should take its first meal from the bucket. Take about four pints of warm milk from the cow, get the calf between your legs, place the left hand around the mouth, with two fingers above the tongue, with the bucket underneath the head of the calf, and then lift up the milk with the palm of the right hand, making sure that the milk is going down the throat of the calf. After lifting up two or three handfuls, the calf will taste the milk and start sucking the finger. Coax the calf's head down with the left hand. Having fed the calf the first time, do not be too anxious to make it drink a lot. After a few days it will drink about 1 gallon at each meal, which should consist of two pints of fresh and six pints of separated milk. At three weeks of age the calf will require something more than milk, and green hay will be found very suitable. Failing this, long chaff, a little bran, and some linseed can be fed. This will carry the calf on for about three or four months, when it can be put into a small paddock. If grass is not available, see that it is given plenty of hay. The milk can be reduced and a little water added. Do not change over too quickly from one form of feeding to another. Keep the heifer calves by themselves and they will be more easily controlled. At about 12 to 15 months old they can be mated. After service, see that the heifers are kept in good condition. At six months of age they should be brought into the bails and given a small feed of chaff and bran once a day for a month and then twice a day. This will be time and feed well spent; learn them to enter the bails and run your hands over them. Always speak to them and it will save much pushing and pulling when they come into milk. It is advisable to accustom the heifers to leg roping. This is very important, for one never knows when sore teats or a tender udder will develop. Sometimes it is difficult to milk a heifer full hand. Try and milk her with a squeeze, even if it is only possible to use the first finger and thumb. When milking a heifer, it is a good plan to squeeze the milk down into the teat and rub the point of the teat with the knuckle of the thumb or finger. Never on any account use the nail or the teat may be injured. (Secretary, Mr. H. Muegge.)

#### UPPER WAKEFIELD.

April 2nd.—Present: 11 members.

**CARE OF THE LAMBING FLOCK.**—Mr. J. Cleary read the following paper:—"As lambing time approaches, it means a good deal of work for farmers, who are generally busy seeding. Foxes are a great trouble, especially among early lambs. It is a good plan to inspect the flock during the day. Ewes often 'get down' during lambing, and assistance can be given to those which cannot deliver their lambs. Often after the lamb is taken from the ewe it appears to be dead, but in a great many cases, with a little trouble, the youngster will recover, and if a little drop of milk is milked from the ewe into the lamb's mouth it will very often recover, and the lamb can be put on the teat whilst the ewe is lying down. When this is done it is well to make sure, before lifting the ewe, to see that she intends to take to the lamb. If not, tether the ewe with a piece of binder cord for a few hours, until the lamb is strong and will follow the ewe. In any case, the ewe generally breaks loose and both walk quietly away. **Marking and Tailing.**—This is very important work, and great care should be taken. Do not tail straight after yarding; lambs are generally overheated and often are lost through loss of blood. Every lad on a farm should be taught how to hold a lamb for castrating. A very important point when removing the testicles from a lamb is not to pull too hard. Pull gently, and take the purse between the thumb and the forefinger, pressing on the stomach at the same time. Injury to the lining of the stomach causes rupture. When letting the lamb go after the operation, bend over the rail and open both hands at the same time, and the lamb will always land on its feet. On no account should a lamb be put down by force. It often happens that one testicle only can be found. If the hind legs of the lamb are released and the stomach pressed, it will generally come down. If it cannot be found it is customary to only 'dock' the tail, so that this lamb can be recognised later." A good discussion followed. (Secretary, Mr. C. F. Neumann.)

#### WIRILLA.

Mr. W. Jones presided over an attendance of 24 members and several representatives of the local Women's Branch, making a total of 50 persons present at the meeting of November 6th, which was held at the residence of Mr. W. Blatchford. Mr. J. Jones gave an instructive address dealing with his experiences on a recent tour of the world. (Secretary, Mr. H. Schunke, Manoor.)

**ERRATUM.—SADDLEWORTH.**

On page 1092 of the May issue the following was omitted from a paper read by Mr. L. Giles:—After the word "breed," line 31, "Their original home is England, and perhaps that is another reason for their popularity. The Friesian is a very old breed; we find it mentioned in history 400 years B.C."

**YORKE PENINSULA DISTRICT.****(TO BUTE.)****BOOR'S PLAINS.**

April 2nd.—Present: 12 members.

**CARE AND MANAGEMENT OF HORSES.**—Mr. G. Rodda contributed the following paper:—  
 "When horses are brought in from stubble feed, have a good clean stable ready for them. Bring the horses in and feed them once a day for a week. They become accustomed to the feed, which will save trouble with colic and scouring, and put them in better order for working. Trim the hoofs, and see to the manes and tails. For feeding, I prefer oatmeal hay chaff. Regular feeding is very important. Give four feeds a day, as near as possible to the same time every day. The manger should be cleaned out at midnight, then the team will have a good rest, and be ready for breakfast. Always feed enough, but be sure the animals clean up what is given them. Horses should have 1½ hours to feed in the morning; three-quarters of an hour at midday is plenty in winter when the days are short. Always aim at keeping the horses in good condition; it takes less feed to keep them, and they do their work much easier. I prefer working two yokes a day. All horses should be groomed every morning with a currycomb. A man who has a 12-horse team, and gives them 1½ hours in the morning to feed, has plenty of time to have breakfast, and do anything there is to be done regarding his team. Have all harness in good order—winkers, couplings, and reins. See that winkers have good bits and rings; if worn throw them away, it is cheapest in the end. Collars should be cleaned every morning before being put on the horse. A well-fitted, clean collar, put on a clean shoulder, will minimise sore shoulder troubles. Never pinch a collar with the hames, it will cause a sore on the top of the neck. Always keep the mane from under the collar. When the team is started off afresh, work short yokes for a few days until they get settled down. Do not work horses after sundown; the sweat does not dry off overnight; half an hour after sundown takes as much out of horses as two hours in the morning. In driving the team, do not push them; they will go their own pace, do just as much work, and do better than the team that is driven. Mares that are used for breeding should be given a little extra care, both in feed and work. They should be kept out of any heavy pulling; ordinary work will not hurt them, if kept in good condition. If one has enough horses to do the work it is better to spell the mare whilst suckling the foal. Keep the mares in condition and they will feed the foals much better. Wean the foal at six months old and work the mare lightly. When the foal is weaned, feed it and keep it in good condition. At three years old the colt should be broken in. This is best done just before harvest. Work half-days for a start until the colt becomes hardened. For breaking in young horses, I prefer a round yard to catch them in. Get a light stick, 5ft. or 6ft. long, rub them

over with it for a while, and in less than 20 minutes a rope and headstall can be put on. Do not put the rope around the neck; put it around the back between the front legs and through the headstall. Tied this way the colt will give in to the rope much quicker. After being tied up for a few days, the colt will lead in a few minutes, and be then ready for the team. Put him behind a quiet leader with a neck rope on and there will seldom be any more trouble." (Secretary, Mr. S. Chynoweth.)

#### PETERSVILLE.

March 3rd.—Present: Nine members.

Harvest reports were given by several members. Mr. C. J. Harmer in a paper, "Care of Farm Tractors," advised every user to see that his machine was always ready for use whenever it was required. After the tractor had been overhauled and was quite ready for the paddock, the fuel tank should be filled with clean fuel. He always liked to have a clear flow of fuel; if not, it would be often necessary to pull the carburettor down, which meant delay. Care should be taken to strain all fuel. Lubrication was an important factor. Most tractors had a simple gauge of some sort. The oil should be always kept up to the level the maker intended it to be. Further, one should be certain that the engine oil was not half diluted with kerosene through neglecting to change the old worn-out oil, as was often the case. *Greasing.*—He had used both the grease gun and cup compression methods of greasing. He preferred the former, on account of the great pressure that could be used. Once a day he found was often enough for greasing, though the cups required frequent screwing up. There was not much required in the lubrication of the gear case, as it was automatic. A modern tractor should last up to eight years. A tractor was never worn out entirely, because parts could always be renewed, but after about eight years it became too costly to be profitable. In maintaining the life of a tractor the user was a much more important factor than the owner. Some drivers never thought of lightening the load by propping up one furrow. Anyone who was used to engines could tell when a tractor was overloaded. The writer liked to hear the engine exhaust bark out sharply when the tractor took up the load. It showed that the engine was not overloaded. A tractor should never be overloaded; firstly, because the engine would run at less than its normal speed, with the result that the governor would open up the throttle and the kerosene would be sucked in, but would not be properly ignited. Thus the unused kerosene was forced past the pistons into the crank case, and diluted the oil, with very bad results to the smooth surfaces of the cylinder walls. A good test to make sure that a tractor was not overloaded was to place the lever of the implement into the soil for about four notches further than the setting that it was intended to use. If the tractor could pull that all right it would be safe enough at the original setting. A 15/30 tractor should not be given a load heavier than a 12-horse team could manage. Twice a year ought to be often enough to do valve grinding and de-carbonising. An old valve should not be kept working too long, since it was an inexpensive item. If the engine started to use too much oil, it might be due to the piston rings being badly worn. To get the best results the carburettor should be frequently cleaned and re-adjusted. The writer's way of adjusting a carburettor was to retard the spark, "rev. up" the engine, and screw up the jet until the engine started to "spit" or to labor. He then opened up the jet until the engine ran free. He found that that adjustment would work well at all times and under any load. Too lean a mixture resulted in a hot engine, and also used a good deal of oil, and thus one would not save by cutting down the mixture too far. A little oil added to the kerosene would assist in lubricating certain parts that could not be oiled otherwise. One should not abuse a tractor by speeding up the engine above the speed recommended by the maker. A high-speed engine would give more power, but also a repair bill. However, he did not like to hear an engine laboring through being driven too slowly or under too heavy a load. The magneto should not be tampered with by anyone except a careful or experienced man. Slipping the clutch was very detrimental. It was often done where the load was too great. It certainly let the engine gain speed, but it caused intensive friction, which would burn or score the clutch plates. If persisted in the clutch would not hold the power of the engine, and new plates would have to be inserted. The transmission and gear case should always be kept full of heavy oil. If that was done there would not be much need to worry. However, under heavy loads and sudden strain the bearings would be sure to need attention sooner or later. It was advisable to have the transmission inspected every two years during the first four years, and after that annually. There was always plenty of time to have such work done during slack months. All nuts on the spider bolts should be kept tight. They held the differential in position, and if allowed to become loose the back-lash would be too great for them, and a breakage would be certain. (Secretary, Mr. A. G. A. Dutschke.)

**WEAVERS (Average annual rainfall, 16.89in.).**

The monthly meeting held on September 8th was attended by 19 members and two visitors. Mr. E. J. Algie read a paper, "Sheep and Wool." He said that when stocking a farm with sheep the first point for consideration would have reference to the number that could be kept to the best advantage on the area available. There was greater wisdom in understocking than in overstocking. Sheep were kept not only to show a direct profit of their own, but to help in cropping, to enrich the land, to keep down weeds, and to turn to advantage odds and ends that would otherwise be lost. Even where general conditions were best known, no one was as yet in a position to state definitely the number of sheep to a given area that farms were capable of carrying to advantage. He was of the opinion that the number was much in excess of what was generally believed to be the case. The farmer who wished to combine sheep with his cropping must not limit their number to what he deemed to be the carrying capacity of his available grazing paddocks at the worst time of the year. In other words, he must always hold himself in readiness to feed his sheep, should occasion arise, by such means as sowing Cape barley on hay stubbles or by conserving cocky chaff. He questioned whether barley was made use of sufficiently on light cultivation for grazing purposes. On some farms more sheep were kept than ought to be. Where such overstocking was carried on results were generally very unsatisfactory, because not only were sheep kept in anything but good condition, but at shearing time results of the clip were disappointing. The number of sheep that could be carried on a given area had always been a difficult question. Before fertilisers were introduced the carrying capacity might have been more easily defined, since the season was practically the only thing to be taken into consideration. Since the use of fertilisers, the number of sheep had increased from time to time. The answer to the question, "What is the happy medium?" must be left to the farmer to work out for himself. If he went slowly and felt his way, the problem would gradually solve itself. For lamb raising, he considered the Merino ewe mated with the Dorset Horn ram would produce a good lamb for market, but it was essential to ring fence the whole of the property with pig netting at least 4ft. high. The light fleeced Merino-Dorset Horn ewes were excellent mothers and probably reared better lambs than any other sheep. Possibly when they became more experienced with sheep and had their farms subdivided into a greater number of paddocks, and in the light of the fact that crossbred ewes were better mothers than Merinos, and, if bred on the farm, more docile than bought sheep, the practice of

breeding their own ewes might become more general with farmers. Years ago it was common practice not to breed from ewes until they were four-tooth or over two years old. He still tried to work on those lines, because he considered that the young ewe needed much more attention during lambing than the older ewe. Frequent reference had been made to the necessity for the sheep being well fed, but it was not less important that they should be supplied with plenty of good water. Of late years the blowfly had become a serious pest to the sheepfarmer, although if the sheep were crutched it would help to overcome the trouble. With the aid of a good dog he found it easier to detect a sheep that was blown out in the paddock than by yarding them. (Secretary, Mr. H. Cornish, Stansbury.)

March 9th.—Present: 11 members.

**REVIEW OF THE 1930 GRAIN HARVEST.**—Mr. J. Bridges read the following paper:—  
**“Barley.**—As the market for this grain was very dull, only the very best was selected by maltsters as suitable for their requirements. The standard fixed for this grain, therefore, meant that very few farmers had a No. 1 line. I submitted over 50 samples of barley, and out of this number only three were classed as being No. 1. Most of the samples were fairly even and were classed No. 3, or feed barley. Harvesting of this grain is not all that could be desired, and farmers are urged to take more care and prevent the skinning of the barley as much as possible. Skinning good barley is not only spoiling the sample, but has the effect of spoiling the sale of the grain. An improvement in the harvesting generally would be of advantage to farmers. **Wheat.**—Samples of this grain were very disappointing, being from very good to only fair. The fact that the standard for this grain was fixed at 60lbs. shows that the quality throughout this State was only fair, some wheat received was very good and free from smut, &c. A few of the best varieties noticed were Nabawa, Marshall's, and odd lots of the numerous varieties now being sown in this district. Gluford and Gluyas were the most prominent of the affected wheats. With few exceptions, all wheat received contained a proportion of barley, a great deal of chaff, and heads of wheat poorly thrashed. Very little smut was noticed. Greater care should be taken in reaping, and a considerable saving in bags could be effected. Quite a lot of good wheat was received, but too much chaff was in the bags, and the weight of this wheat would vary from 160lbs. to 190lbs. in the bag. If only from an economical viewpoint, every bag of wheat shipped away should contain nothing less than 190lbs. Greater attention to the filling of the bag from the harvester means more wheat in the bag. As the return in cash to the farmer is fixed by the value received overseas, it is apparent that greater care should be taken, and every farmer should see that every bag of wheat and barley is marketed in quality as well as quantity. Weather conditions have not been favorable to cereal growers during the past season, and a return to normal conditions, both in weather and prices for grain, would be most acceptable to everyone.” (Secretary, Mr. H. Cornish, Stansbury.)

#### WESTERN DISTRICT.

(CLEVE (Average annual rainfall, 14.61in.).

April 9th.

**BLACKSMITH'S SHOP ON THE FARM.**—The following paper was contributed by Mr. T. Slater:—“There should be a blacksmith's shop on every farm, for, with a little experience, every man can soon do the most, if not all, of the small jobs necessary on the farm. The building should be erected at some distance from other buildings, to minimise the danger of fire. The shop should be designed to admit plenty of light to enable one to do the work properly. Good light is necessary when tempering steel, such as picks, crowbars, chisels, &c. With a small bellows or a blower one can get a fire strong enough to do the most essential work. I favor the forge with what is generally known as the ‘fire pot.’ This will enable one to have the fire well in the centre of the forge and give room for shaping and bending iron necessary for some jobs. Most of the blowers are supplied with the ‘fire pot,’ and with the top of an old

200-gall. tank with a stand, or leg bolted to each corner, one can rig up a good forge. The anvil should be at least about 1½ cwt., vice, drilling machine, taps and dies ranging from about ½ in. to at least 1 in., two or three hammers of different sizes, tongs for handling different sizes of iron, a couple of good cold chisels, and a set of spanners. A good anvil cutter can be made from an old three-cornered file, if tempered down to prevent it from breaking. At the present time coal is an expensive item, but if one can obtain good charcoal, a lot of work can be done with that, such as the sharpening of tools and shares, bending and shaping iron, in fact, most work where welding is not necessary. Welding at first may seem difficult, but with a little experience the farmer would become quite an adept at it. A clean fire and the correct heat are the main factors. Sea sand makes a good flux for welding, it helps to keep the iron clean, and goes a long way towards preventing it from burning. On wet days or in slack times the farmer can do a good deal of work in the shop, such as repairing chains, making hooks, eyebolts, sharpening picks, crowbars, drawing out shares, making a supply of split-links, which are always handy in the paddock should a chain break. A couple of spare hooks and eyebolts are also always handy in the tool-box of any implement. There is a lot of work that can be done if there is a smithy on the farm, and it will save a great deal of time and expense that would otherwise be necessary if the job has to be taken to a township, which may be miles away. Although it may be expensive to set up a small smithy, counting time and expense, the blacksmith shop will not be long in paying for itself." (Secretary, Mr. H. Matthews.)

#### ELBOW HILL (Average annual rainfall, 11in. to 12in.).

March 3rd.—Present: 10 members.

**PORK AND BACON INDUSTRIES.**—Mr. J. Rehn spoke on the possibilities of the pork and bacon industries and fat lamb raising in this district. With wheat and wool at their present low prices, other means of making money should be sought after. In England there was an unlimited market for pork and bacon of the right type. The pigs he favored were the large white Yorkshire and the Tamworth-Berkshire, which did not produce fat more than 1 in. thick from the shoulders back. There was a good supply of second-class wheat and barley about, which, if not marketable, could be fed to pigs. The biggest difficulty was getting to market at the right time. Mr. S. Wake said little could be done without better organisation. There was very little difficulty raising and marketing pigs years ago. Mr. G. Payne said the difficulty could be overcome by writing to the Government Produce Department. There should be money in pig raising. Eggs were bought from farmers around Cowell within ½d. of Adelaide prices by the Farmers' Union. Perhaps the same could be done with pigs. Mr. Wills said if farmers had spare time they could have side lines. Every penny made now is new money to help the farmer to remain solvent. Mr. W. Cooper believed in side lines or mixed farming. They were a good help now that wheat and wool were so low in value. (Secretary, Mr. W. Cooper.)

#### CUMMINS (Average annual rainfall, 17.77in.).

March 13th.—Present: nine members.

Mr. R. Olsson submitted an extract on the subject "Lowering Production Costs." A good discussion ensued. **Depth of Ploughing.**—Mr. M. Palm asked for opinion of members on this matter. Mr. H. Smith said it depended on the type of land and the district. Mr. H. Roberts said experience led him to favor fairly shallow ploughing, the result being quite as good and less expensive. His land was mostly of fairly heavy type to work. Mr. E. Fitzgerald favored good solid ploughing for new land, and about 2½ in. deep for old land. He said disc implements had done good work for him; they were light in draught and knocked the shoots about. He favored mouldboard ploughs where they could be worked. Mr. F. Jericho favored the share plough where it could possibly be worked. Messrs. Palm Bros. only used disc implements when shoots and rubbish made it necessary. Members were agreed that deep ploughing was not necessary in this district on old land, 2½ in. being sufficient, but new land should be ploughed early to a depth of about 4 in. to break up roots and runners in the soil. **Rate of Manuring and Seeding.**—Members seemed of opinion that tests had demonstrated that 1 cwt. was necessary. Considerable difference of opinion existed on this subject. Some members advocated 40 lb. to 50 lb. graded seed for best results; others favored 70 lb. to 80 lb. per acre. The Secretary promised to carry out an experiment with the object of recording the result of 45 lb. per acre and 75 lb. per acre. Messrs. Palm Bros. promised to conduct a similar test. (Secretary, Mr. H. Roberts.)

#### KOPPIO (Average annual rainfall, 22.40in.).

March 10th.—Present: Seven members and three visitors.

**SUPER WITH CEREALS FOR GREEN FEED.**—Under the title "Does it Pay to Sow Super with Cereals for Green Feed," Mr. R. Schultze read the following paper:—"In 1929 I sowed 8 acres with rye and oats at the rate of about 1½ bush. and 200 lbs. of super to

the acre. This pasture was stocked in August with two horses, six head of cattle, and aged ewes. All stock when put in were in poor condition; in November they were all turned out, but after a few hours all returned and kept on picking off the 8 acres which appeared to be very scarce of feed. All of these animals were in good condition. One ewe weighed 62lbs. when dressed. During pasturing most of the ewes lambed, and the lambs at shearing time—12 months later—were much larger and stronger than other lambs which had a large run of grass and herbage which appeared to be much better as far as quantity goes, but had not been supered. In 1930  $4\frac{1}{2}$  acres were sown in addition to last season's plot. Some of the Subterranean clover had been topdressed. Rain came late, and as a consequence, feed was late. In August 200 sheep cleared out the 8 acres, of which there are about 2 acres of Subterranean clover. In September all stock were shifted, except nine ewes, six head of cattle, and 10 horses. The horses were given a feed of chaff twice a day for a while. When the chaff was all gone they depended entirely on the 12 acres, and results are equal to last year so far as the condition of the stock is concerned." (Secretary, Mr. M. Gardner.)

#### KYANCUTTA, April 22nd.

Mr. R. Bedford gave an interesting address, "How to Improve Farming Conditions Generally to Cope with Low Price for Wheat." A Question Box was also on the agenda, and many questions of interest were asked. It was asked if pig raising could be made a profitable sideline on the farm, and it was decided that such would not be so unless producers could be assured of a market at Port Lincoln, when under such circumstances it could be made profitable. In a question regarding poultry, it was decided that the Utility Black Orpington was the best breed for the farm; it was a good layer and table bird and did not fly on to haystacks or do much damage. It was agreed that if a little time was spent on the homestead garden, enough fruit and vegetables could be grown for one's own requirements. As to the best type of ram to mate with Merino ewes for raising lambs for freezers, the Romney Marsh was spoken of favorably. It was decided that the share plough was the best implement with which to plough the soils of this district. The disc implements met with strong disapproval on account of the land having a tendency to drift. It was agreed that it did not pay to crop land more than three times in succession with wheat in this district, and preferably the third crop should be oats. (Secretary, Mr. D. Fitzgerald.)

#### LAURA BAY.

December 9th.—Present: 12 members.

**AFFORESTATION.**—Under the title "The Advisability of Leaving Timber Standing on the Farm," Mr. W. Bowen read the following paper:—"There is a clause in each farming lease to the effect that it is necessary to leave five acres of standing timber in every 100, but it is left to the discretion of each leaseholder as to where it shall be left. I do not agree with the suggestion that each leaseholder be compelled to leave a strip of timber two chains or more in width all round the boundary. This may be advisable in some cases—where the soil is of a light, sandy nature, which drifts easily—but on such holdings more than this is needed. No paddock should be more than 150 acres, and a break left around each. To those who have land of the nature first mentioned and have still most of their timber standing, I would say 'leave all the breaks you can,' but on land that does not readily drift, leave a fair size patch for firewood, and also smaller patches and odd shady trees in every paddock for shelter for stock. It is not much bother to work around these small patches and odd trees, and one is well repaid for the trouble by knowing that the stock can shelter from the hot sun or cold winds without travelling very far. Were it not for the expense, it would pay to fence both sides of breaks on sandy soils, because where the stock have free access to these breaks, the undergrowth is soon killed and the mallee and other trees soon die out. Further, when the undergrowth is destroyed the wind break loses half its value, unless the break is several chains in width, and too much of that sort of thing means that one is paying away a lot of rent, rates, and taxes for land that grows no feed. If a break of two chains is left around the farm, it will probably mean that you have three chains that are profitable from a grazing or cereal growing point of view. One seldom sees any vegetation within one chain of the break. However, the matter is best left to each individual farmer. He should best know the peculiarities of the soil on his own farm. Sometimes it may happen that a farmer has perhaps a strip of land of a drift nature, while the rest of his farm does not drift. This, of course, would need breaks. So far as this district is concerned, it is too late to worry much over the matter, the majority of blocks having been cleared of most timber." (Secretary, Mr. W. Edson, Ceduna.)

MANGALO (Average annual rainfall, 14in. to 15in.).

April 13th.—Present: 19 members.

**DESTRUCTION OF VERMIN.**—"Of first importance so far as farm pests are concerned is the rabbit," said Mr. O. Hanneman in a paper on the above subject. "If starting on an holding overrun with rabbits, the best way to reduce the number, and by far the quickest, is the poison-cart. This method should be followed up immediately by the complete destruction of all burrows or any other harbors that may exist, then if there is any sign of stray rabbits about, set traps. It will be rather a slow process, but time well spent, for if you do not persevere you will have the same work to do all over again. The best method of destroying foxes is to make a trail by dragging the paunch of a sheep and lay strychnine baits. *Mice.*—These pests give quite a lot of trouble about the house, barn, and hay stacks, and to fence them out is a big undertaking. They can be fairly easily destroyed with poison. Take a small quantity of the best fat, mix a little strychnine into it, place a little of it on pieces of board or wood, and set it out where the mice are doing damage. They will take the baits amongst wheat or flour, but it must be fresh. Do not leave the baits out over the first night, and if there is any danger of any other form of animal life getting it, gather it up and burn it." (Secretary, Mr. C. Hannemann.)

#### PALABIE.

April 3rd.—Present: 12 members.

**PREPARATIONS FOR SEEDING.**—Mr. E. Rashleigh read the following paper:—"In preparation for seeding, fallowing is undoubtedly the correct method of farming. Unfortunately, we have been unable to get the ground cleared so as to have fallow, but we should aim to have some fallowed land as soon as possible. For light soils, the best implements are a skim plough and harrows. A cultivator is a very useful implement for working the land just before drilling in the seed; it loosens the soil to a greater depth than the harrows. In working light soils I favor ploughing to a depth of 1½ins. to 2ins., and then using the harrows as much as possible when the weather is suitable. Fallowing in February and March gives one more time to attend to the fallow. It receives all the winter rains, and as soon as seeding is finished a start can be made to work back the fallow. See that seeding implements are in good condition. Take a note of any spare parts needed at the finish of seeding and get them on hand, and then in spare time the machines can be made ready. 'A stitch in time saves nine' especially

applies to farmers; a spare part got in early may save a week's waiting when you should be hard at seeding. If seed is to be dry-pickled, get it done early. Pickling with bluestone can be done a fortnight ahead so as to give the grain a chance to dry." Mr. W. H. Brownrigg (District Agricultural Instructor) addressed members on "The Value of Side Lines." (Secretary, Mr. E. Bockleigh, Wudinna.)

PYGERY.

March 31st.—Present: 22 members.

HORSES V. TRACTOR.—This meeting was conducted by the junior members of the Branch, Mr. Humphries being elected Chairman and Mr. J. Edmonds Secretary. Mr. D. Heath read the following paper:—"It is easier to start farming with horses than with a tractor, because a tractor is more expensive to buy than a good team of horses, and there is at least five years more life in the horse team than the tractor. A horse farmer can build up his team by breeding two or three foals every year, and after paying the expense of a good sire, there is no more cost until the breaking-in of the horse, and then £3 will buy the necessary harness, which if carefully looked after should last more than the life of the horse. The horse has helped to buy most of the tractors in this district. If one horse becomes ill, it is quite possible to carry on the job with one less, but if a part of the tractor is broken in the middle of seeding or harvest the tractor would be idle for perhaps a week waiting for the part to be replaced. When harvesting a crop with tractor and harvester, it requires two men to operate, but one man can drive a team of horses and a harvester, and there is no danger of fire with horses. The money expended on the purchase of a tractor and fuel is sent out of the country, but horses and harness are products of Australia." (Secretary, Mr. A. Day.)

ROBERTS AND VERRAN.

February 4th.—Present: 14 members.

MIXED FARMING.—Mr. J. Pahl read the following paper:—"Sheep and their products are regarded as the chief asset in mixed farming. I favor the Merino for wool and lambs, and consider sheep the chief side line. On every farm cows are to be found, generally keeping the house in dairy produce, with a little surplus. I do not think our market warrants the expense of keeping a large herd. For general purposes I favor the Jersey or Shorthorn. In conjunction with cows, pigs can be successfully carried. Given plenty of milk, pigs thrive well; and as oats or barley have to be grown for rotation cropping, these can be fed to pigs, and will in this way return market value. The Tamworth-Berkshire cross is ideal for bacon and early maturity. Fowls also play an important part in farming, and if proper houses and yards are provided, they will prove a most profitable side line. Besides producing eggs, birds could be grown for table use. One hundred fowls kept properly and fed regularly will be found sufficient for most farms. Black Orpingtons and White Leghorns are good layers, and when crossed make good table birds. Last, but not least, is the farm garden, this plays a very important part in reducing household expenses. Almost every variety of vegetable can be grown, provided plenty of water is available. The garden should be protected by a brush fence against prevailing winds. Plenty of manure is essential for success." (Secretary, Mr. C. Masters, Verran.)

March 4th.—Present: Eight members.

FARM MACHINERY.—The following paper was contributed by Mr. S. Barber:—"With wheat prices at such a low level one needs to consider well which implements will serve best before making a purchase. For working the ground for seeding, I prefer a cultivator or skim plough where it is practicable to use them, because not only do they make a better job of working the ground than a disc implement, but they break more roots and are less costly in upkeep. Shares for these two implements are practically the only thing (other than oil) on which there is much wear. Cultivator shares can be purchased for about 1s. each at the present time, which will give long service in this country. Skim plough shares can be made on the farm at a cost of about 6d. per piece if one purchases the steel in bulk. For planting the seed, I prefer a disc drill is preference to the combine, because the drill is less costly to operate, does not give the land a tendency to drift, and can cope with more rubbish than a combine. For fallowing I favor a good plate plough, because it cuts and turns all ground at an even depth—something which cannot very often be said about a disc plough, because of the side play and wear in the disc box. They are costly to replace, and, therefore, are not replaced as often as should be, hence a bad job is made. For hay cutting I prefer a binder not more than a 6ft. cut, because a binder is a machine that is not used at any other time of the year and does not, as a rule, do a very great acreage, therefore I do not think a wider cut than 6ft. is necessary. The owner of a binder should always drive his own machine, because it is an implement that requires a little more care and attention than the average farm implement. Attention to lubrication,

tightening of bolts, correct tension of string, and correct setting of packing table, &c., are points that are often overlooked. The binder should be put in the shed immediately the binding is finished. For chaff cutting a cutter that will put through from two to three tons per hour is not too big, and will save a lot of time. To drive a cutter this size it is necessary to have a fairly powerful engine, one of about 8 H.P. to 10 H.P. In purchasing an engine it is advisable to have a portable one, because not only is an engine used on the chaff cutter and corn crusher, but it is essential to have an engine for the power winnower and various other jobs on the farm. The harvester is favored for taking off the crop. I admit that there is a fair margin in favor of the harvester over the stripper and power winnower when purchasing, but that is not the only aspect of the question. It requires eight horses to work a 9ft. harvester comfortably with chaff carrier attachment, whereas the same number of horses will work two 8ft. ordinary strippers, therefore several acres a day more can be reaped with the same number of horses. By this comparison it can readily be seen that there will be a big saving in horse feed by the time harvest is finished. This is not the only advantage the stripper has over the harvester. Bearings are another factor. There are at least three times the number of bearings on a harvester (besides various chains and belts) than on an ordinary stripper. A stripper will last for years longer than a harvester, particularly if light crops are being handled. For wheat cleaning the power winnower saves a good many bags of wheat in a year by thrashing all heads that were not previously thrashed. It also saves a lot of time and trouble. This machine, like all other farm machinery, should be repaired if necessary and put in the shed immediately harvest is finished."

The meeting of April 1st was attended by 15 members, when a paper, "Breeding and Breaking in Colts," was read by Mr. A. Ramsey. (Secretary, Mr. C. Masters, Verran.)

April 21st.—Present: seven members.

SEEDING OPERATIONS.—Mr. H. Smith contributed the following paper:—"Seeding operations start with fallowing. Fallowing consists of the preparation of a good seed-bed and gives best results if kept in good condition, free from weeds. Sowing can be commenced as soon as a good rain has fallen. In this district oats may be sown in April and wheat from the 1st of May to the middle of June. Dry pickling has several advantages over the wet method; the seed germinates more quickly, and pickling can be done any time between harvest and seeding. A disadvantage in using copper carbonate is that if inhaled it causes an irritation of the nose and throat. Further, it is liable to clog the drill. The drill should be turned every morning before starting to save breakages. Bluestone is more pleasant to work with and gives good results. No wheat that contains smut should be sown. All land should be well cultivated before seeding. I favor the disc drill for sowing, and all land harrowed where possible two or three days after sowing, to pack the ground and loosen the surface so that all plants can get through. Where land is of a drifty nature, it should be left as rough as possible. When new land is to be sown it should be ploughed early, wet or dry, because the crop will have no weeds to contend with. If a clean burn is secured, a foot plough should be used, otherwise the disc is better in sticks, &c. When rains are late, new ground may be drilled in dry with fair results, and new land should be harrowed after sowing to level and pack the ground. See that all implements are in good order when starting; have a few spare swings, books, &c., on hand, and horses in good condition, so that seeding may be completed without hindrance." (Secretary, Mr. C. Masters, Verran.)

STREAKY BAY (Average annual rainfall, 14.91in.).

November 21st.—Present: 13 members.

SAND DRIFT.—Mr. J. Drever read the following paper:—"Having been farming on light, sandy soil for over 20 years, I claim to have had some experience of sand drift. Prior to this country being cleared for farming, there was very little drift, therefore it is apparent that clearing all the natural growth off the land increases the risk of drift. Unfortunately, many thousands of acres have been cleared without any thought as to whether it would drift or not. It is now well known that the tops of many high hills do not grow very good crops or very much feed, and are the starting points for much of the drift, and should have never been cleared. Another very serious cause of drift is overstocking in dry periods, especially with sheep. It can be safely said that if a horse, a sheep, and a cow in equal condition were placed in a three-acre paddock to live on the natural growth, the majority of farmers would agree that the sheep would live the longest. Therefore, they must be the worst offenders in eating out all the protection the land has from wind. Sheep also have a habit of camping on high hills on hot days, and they dig holes there, and eat out the grass roots and leave the hill in such a condition that the sand moves about with every wind that blows. Sand drift is worse than fire. It will kill crops and feed, cover and render useless fences and other

improvements, and if it continues year after year, the soil becomes poor for the want of organic matter. It is then a difficult matter to get anything to grow on the soil. A paddock or a farm that gets in that condition is a source of worry and expense to the owner, and will eventually ruin him, unless the drift is checked. Any preventive methods that may be used must depend largely on the locality and materials that are available. When clearing scrub, breaks should be left, especially on high ground and on the tops of hills that are considered to have poor soil on them. Where land has already been cleared and begins to show signs of drift, sheep should be kept off it, even if they have to be sold on a poor market, because, if by selling them the land is saved from drifting, it will pay the farmer to be without them until the land improves. In many cases if the most likely places to drift are not fallowed, but watched and farmed carefully, drift can be prevented to a great extent. On the extreme tops of hills, where drift first shows signs of starting, it is a good plan to make some sort of a break—either brush, stones, stumps, or straw will answer the purpose. If they are placed in lines so as to form a square, say a chain each way on the worst part and larger squares around, it will have some effect on the drift. Where there are big areas of drift, all efforts to control it should be made on the northern, western, and southern sides. Much has been said about keeping a ridged surface on this class of drift, but unless there are plenty of grass roots in it, any attempt to keep the surface rough will be wasted, for it will take very little wind to level it out again. I favor sowing this class of drift with a quick-growing wheat that does not stool very much as soon as possible after the first good rain. If the plants get a start early in May, they will grow quickly while the ground is warm. Any weeds or grass that are likely to grow should be encouraged. Rye is a very good plant to withstand drift, and would be well worth trying on some of the worst patches. Cross drilling with double the amount of seed will also have some beneficial effect. Should a crop be cut with drift just after it comes up, much good will be done by coupling up as many horses as one can conveniently manage and driving them up and down the worst sides. A large area of land can be got over in a day, and the tracks of the horses would have to be filled in before drift could do any further damage. Wheats that stool well, or malting barley, will not stand the same amount of drift as a variety of wheat that grows up quickly. Should a farmer be fortunate enough to get a crop on three parts of a drift paddock, it will be wise to leave the stubble as high as possible and cart straw on to the patches that are still drifting. Sow again the following season, and keep all stock off the paddock until it gets a good coating of vegetation." Mr. P. Anderson read a paper, "Farm Book-keeping." (Secretary, Mr. C. Thom.)

WADDIKEE ROCKS.

March 7th.—Present: 12 members.

BIRDS, THE FARMERS' FRIENDS.—Mr. W. Heir read the following paper:—"Many farmers have noticed how often starlings are seen on sheep's backs. If there are any lice or ticks on the sheep they will pick them out of the wool. These birds are very fond of figs and other fruit, but they make up for that in the good they do by killing many grubs and insects. The "Willie Wagtail," or Shepherd's Companion, is often seen around sheep, and if they are allowed to get tame around the house, will fly in and kill a large number of flies. It is one of the best bird friends we have. The small brown bird is a great worker at killing all kinds of small insects, and their nests should never be destroyed. I believe the Crow does a great amount of good by keeping down the blowfly pest, which is a great source of loss to all sheep owners. The Magpie is a very good friend to farmers and kills a great number of insects and flies. There are a number of other birds of great value—the Ibis is one of the best, and we should never kill or hurt any of these birds; they are great mousekillers. On the occasion of the last great mouse plague, the Ibis came along in large flocks, and it was interesting to see them killing the mice. Night-flying birds.—We have referred to a few of our day friends, but we must not overlook our quite as valuable night friends. We have the Mopoke in our district, they do an immense amount of good in killing mice and other vermin. There are a few owls in this district, and these render very valuable help to farmers. Let us do all we possibly can to discourage boys from bird nesting. They are doing themselves, as future farmers, a great wrong. Encourage them to be kind to all birds, and instead of breaking down their nests to help the birds by breaking down under branches that might assist foxes or cats to reach the nests. A Bird Protection Club would be of great benefit to all farmers. Boys should be taught to recognise the useful birds and to do all in their power to protect them." (Secretary, Mr. V. Matthews, Kyancutta.)

April 14th.—Present: 12 members and three visitors.

TRACTORS V. HORSES was the subject of a paper by Mr. G. A. Graph. He said that tractors did not require the same amount of attention as horses, and not so many farm implements were needed as were necessary where horses were used. Where the farmer

was a long distance from water, horses were at a great disadvantage, because it would be necessary to use a truck for carting water and its upkeep would equal the cost of repairs to a tractor. The petrol used for a truck would take a large amount of the kerosene account for a tractor, because 1½galls. of kerosene could be bought for the price of 1gall. of petrol. It would take 6galls. of petrol per week for water-carting, which would allow an additional 20 acres to be put in at the same cost as where horses were used. In addition, one saved a day's work at water-carting, in addition to the extra hours gained while horses were feeding. A point for consideration was the extra sheds and yards required for horses. They required both time and material to make. Fencing was also necessary with horses. The use of a tractor saved time during the lunch time spell, and at night horses required a great deal of attention. If a block could be grazed with sheep, the profits from the wool and lambs would pay for the kerosene used by a tractor. Sheep also improved the land for wheat-growing by packing fallow, keeping down weeds, and manuring the land. He considered that the cost of horse breeding would almost equal the price of a tractor. He submitted the following figures:—Horses: 20-hoe combine, £120; binder, £90; chaffcutter, £50; engine, £100; lorry, £260; harvester, £220; harness, £50; water tanks, £10; trough, £5; feeders, £5; chaffroom, £20; yards, £5; 10 horses, £200; total, £1,115. Tractor: Combine, £120; harvester, £220; lorry, £260; tractor, £400; total, £1,000. Working expenses:—Horses: Hay, 30 tons at £3, £90; petrol for water carting, £17; set tyres, £40; repairs to truck, £20; repairs to harness, £10; oil for lorry, £3; petrol for chaffcutting, £5; binder twine, £3; repairs to binder, chaffcutter, and engine, £10; man's wages for water-carting and general assistance, £100; man's board, £50; repairs to fences, £10; total, £258. Tractor: Kerosene for fallow, £35; seeding, £19; harvesting, £25; truck tyres, £40; repairs to truck, £10; petrol for wheat carting, £25; repairs to truck, £20; total, £139. No allowance has been made for profits from grazing sheep on land otherwise used for growing horse feed. (Secretary, Mr. V. Matthews.)

WALLALA.

March 11th.—Present: 11 members.

SHEEP AND WOOL.—Mr. W. Baldock read a paper on this subject, in which he gave his experience with sheep over a period of years in these districts. In the discussion that followed, Mr. H. Brown recommended that ewes should not be too fat when mating. He recommended the Merino for these districts. Mr. Agars recommended the Merino. He stated that sheep carrying heavy and dense wool would not do so well in the lighter rainfall districts as the sheep carrying the lighter class of wool. (Secretary, Mr. C. Zippel.)

WARRAMBOO.

March 4th.—Present: 12 members.

IS IT ADVISABLE TO CONTINUE TO GROW WHEAT?—Under the heading, "Shall We Put in a Crop this Year?" the following paper was read by Mr. F. Daniel:—"This is one of the most important questions of the moment. Never before in the history of the Commonwealth, and probably not ever before in world history has the farmer—the wheat producer—been in the unenviable position in which he finds himself to-day. For four years wheat production in this State has been carried on at a loss. Of the various reasons, the prolonged and abnormal drought conditions have been a largely contributing factor. Undoubtedly, this, combined with the record low prices ruling for our commodities, has rendered what has proved a better growing season of less avail. Farmers are in an unenviable position. Years of hard labor have gone into their farms, which are heavily mortgaged. Many farmers are saying, 'Why put in any crop this year, or accept any assistance to do so, when we know full well, even with heavy yielding crops, our efforts must prove another heavy financial loss while the present wheat values and conditions exist.' Others reply, saying 'How are we ever going to better ourselves if we remain idle?' I cannot see how any farmer in the mallee districts can afford to allow such a thing come to pass. The mallee lands must be cropped to remain clear and of any value. Now if an inspection is made of the result of the inquiry by Professor Perkins, Director of Agriculture, and published in the April issue of the *Journal of Agriculture*, one will find that it is said that the costs of production on Eyre Peninsula are very much lower than to be found elsewhere throughout our State. With wheat below 3s. a loss seems inevitable, but will probably not be so great as would be the case if the farmer did not put the crop in. First, we would have the heavy depreciation of our improved land values, whereas by cropping again that value would be rendered greater. And then it is said, 'The whole community is dependent on the farmer,' but at the present time this is hardly so. The farmer assuredly remains the backbone of the country, and yet at the present time he has been rendered dependent on others. If assistance for another seeding is forthcoming, the best course for farmers to pursue is to put in as much crop as they can really well, sowing about

40 lbs. super to the acre with the minimum amount of seed, and giving the ground the maximum amount of working. Further, as profit on wheat growing has become so uncertain, it behoves every farmer to endeavor to become as self-supporting as possible. This means more side lines. Poultry, pigs, and possibly cows, but essentially sheep. The farmer would be wise, on entering on the side lines mentioned, to select only from good reliable stock and use his crop yields to maintain same. More attention might also be given to orchard work and gardening, and plantations or forest timber. Efforts carried on in these lines would materially assist the farmer to become more self-supporting, and the enhanced value of his holding, together with profits in his business, would in time free him of his present heavy liabilities. In support of this theory a comment might be made on the vexed problem, tractor *versus* horses. A farmer can feed and maintain the strength and usefulness of his horses from the direct product of his ground, but can the same be said of the tractor? An honest endeavor should be made by all to crop as large an area as possible, use as much of their crop yields to raise profitable side lines, and endeavor to get more of their living by direct production of essentials. Continued production is the only way out."

FARM ECONOMY.—Mr. E. Oswald read the following paper:—"First it is necessary to distinguish between false and real economy. Our living expenses have already been reduced to a minimum, as also has money that should be spent on recreation. These items should in reality be the last to suffer from economy cuts, but, unfortunately, they are usually the first. The altered position of wages to hired help makes a considerable difference from the viewpoint of small machines and labor-saving devices and implements to what we have previously seen. It will pay farmers to make shift with smaller machines and teams, and employ extra labor, than to incur new expenses in the purchase of up-to-date machines. The combine has been adversely commented on as a seeding implement for mallee farms—its one point in favor as against drill and cultivator being economy of labor. This will now possibly disappear. Perhaps our greatest economies should be in the direction of smaller areas sown and under better conditions—that is, good fallow and proper rotation of crops, obtaining a good class of breeding animals and adopting fat lamb raising, and poultry. The economies to be aimed at in these directions are the introduction of a good class of bull for dairy cows, and increasing the number of good cows kept; to get a good class of ram for the sheep flock, and adopt the best methods of improving by line breeding. Poultry, perhaps, offers one of the best side lines, and I would refer members to Mr. Anderson's views as published on page 748 of the February *Journal of Agriculture*. Our present method of selling eggs to a local store is wasteful. In connection with the projects that we should adopt in reconstructing our farming practices, we should co-operate and thereby reduce expenses. There is a considerable economy to be effected in the buying of our requirements in bulk and by co-operation." Mr. P. Daniels, speaking on sheep on the farm as a paying side line for profit, pointed out that he had 300 sheep on his farm. He sold his wool in Adelaide at 4½d. per lb. this year, and received a cheque for £34. Out of this he had to take the cost of shearers, woolpacks, carriage and freights, besides the interest on the capital outlay for his flock. Mr. O. Murphy thought that the sowing of less wheat and going in for more side lines meant that the farmer would have to leave out more land, and this would mean that he would have to scrap a lot of machinery, especially if he went in for more sheep. Mr. Daniels said if the farmer decided to go in for more sheep he would still be obliged to grow wheat to have the stubble for grazing. Mr. A. Collins thought that, although wheat growing at the present time was not a paying proposition, the farmer would still have to continue to do so, as he would find that his land would deteriorate considerably if left unworked, and the shoots of the mallee would soon get up again, when the farmer would be compelled to deal with them as before. Mr. Murphy thought the growing of wheat, combined with a few sheep and possibly a cow or two, should be the aim of every farmer. Mr. F. Chilman was of opinion that it would not pay to lose sight of the fact that, if the farmers of these districts decided to grow less wheat and go in for more sheep, they would be taking a step in the wrong direction; owing to the newness of the land the farmer had to continue working the land in the new districts to combat and destroy mallee shoots, and to put the land in heart to grow the necessary feed for sheep. He mentioned instances in districts where the farmer had decided to go in for more sheep and less wheat. They had found it not so profitable as they thought it to be, and had disposed of the greater part of their sheep and returned their efforts to wheat growing. This, he thought, was proof enough that the growing of wheat and sheep was essential on the farm. (Secretary, Mr. E. Adams.)

April 8th.—Present: eight members.

SPORT AND RECREATION.—"Is Amusement Essential to the Farmer?" was the title of the following paper read by Mr. O. Murphy:—"The old saying, 'All work and no play makes Jack a dull boy,' is as true of the outdoor worker as of the man whose occupation keeps him indoors. All may not agree that amusements or recreation of some

sort are essential, but few will deny that they are necessary. We are passing through a very difficult time at present. The farmer must reduce his costs of production. He can do so by dispensing with hired labor, and by increasing personal efforts. The times appear to demand more work, less play, and unfortunately less pay. But the fact should not be lost sight of, that time spent on a reasonable amount of rest and recreation will not necessarily mean a reduction in the amount of work accomplished at the end of the year. Leading minds in the industrial and education world recognise that the attainment of sound, healthy minds is not possible without due attention to the attainment of sound healthy bodies. Our public schools and universities encourage games and sports in the interests of good bodily health and development; in some instances, the participation in some form of sport is compulsory. In practically all industries and professions in this country, the worker and professional man has Saturday afternoon to devote to sport and recreation. The farmer is more or less a free agent. His work in the field is conducive to good bodily health and development. He can, if he wishes, work the full six days of the week, but apart from the question of the value of recreation, the fact is frequently lost sight of that the farmer has to compete for labor with other industries in which the Saturday afternoon has long been recognised as a free afternoon for the worker. If we as farmers wish to compete successfully for a good class of labor, we must recognise the claim of the hired man for a free Saturday afternoon, even though it may mean a suspension of work on Saturday afternoons in the busiest periods of the year, seeding and harvest times. Our recognition of the value of recreation and sport will not, in the opinion of the writer, decrease the efficiency of the work done on the farm. Rather will it tend to make farm life more attractive. The sons born and bred on the farm will be more likely to stick to the land when they reach manhood. The laying down of a tennis court on the farm, or the construction of a cricket pitch, on public grounds are probably better investments than we are wont to think." (Secretary, Mr. E. Adams.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

KANNI, December 13.

THE ADVANTAGES OF THE AGRICULTURAL BUREAU.—Mr. A. Koch read the following paper:—"The object of the Bureau is to assist the man on the land. Members should be encouraged to ask any questions of interest to men on the land concerning which they may require advice. The meetings enable them to discuss subjects that are of vital importance, and members can benefit by the experience of others. The necessity for regular attendance is of great importance. This usually indicates those who appreciate the privilege of being a member. No one expects a member to attend every meeting, as

circumstances at times with apology. This will be most encouraging to the Secretary and the Branch itself, who will understand that the absentee has the welfare of the Bureau at heart. If a member does not wish to attend the meetings any longer, he should notify the Secretary immediately. The Secretary has to notify every member of the Branch concerning meetings, and finds it hard and sometimes apparently a waste of time when only a small percentage respond to their duty. Homestead meetings and social evenings are of great interest to Bureau work. On these occasions members can get in touch with their friends and explain the aims and objects of the Branch. This would show a good spirit and the outsider would soon realise the benefits derived from the Agricultural Bureau." (Secretary, Mr. J. Woodhead, Waikerie.)

KULKAWIRRA.

April 14th.—Present: 14 members.

BEST SEEDING IMPLEMENT.—Mr. L. Jolly contributed the following paper:—"I prefer the mallee type trip-tine combine, with high and wide wheels; it is light in draught, and has a good clearance. A combine has many advantages over a disc drill, especially in stony country. It will go under and push aside a large portion of the obstacles, whereas the disc implement rolls over the tops and leaves the seed lying on top. A combine does away with one man in seeding time, and cultivates and drills

Mr. A. Wedd, who at the Pruning Competitions held at Mypolonga on June 4th, Won the Fruit Tree Section, Tied for First Place in the Vine Section, and obtained the Highest Aggregate Points in the Competitions.

in one operation. It is a mistake for a farmer to seed with a combine on a scrub block, because there are many loose stones and bushes. This implement will pass through stumps and stones up to approximately 1ft. in diameter without any trouble, and about 60 per cent. of the bushes, such as appear on new land, providing they are not more than one year old. There should not be very much trouble in putting in stubble ground, providing a good job has been made of burning. If the straw is light, it should be knocked down before fire raking. When combining stubble ground, roots of the previous crop give a little trouble; they collect around the boots and cause weeds to heap up on the roots. This can be remedied by pulling the tubes out of the boots, but it is then necessary to pull a light set of harrows behind, because the back row of tines does not bury the seed sufficiently. In many cases the tubes on a combine have been known to last three years without any renewal. Do not attempt to fallow with a combine, unless the work is done very early, so that weeds can be destroyed before they are

too well as d A combine has small shares compared with a cultivator, thus allowing large weeds around the tines without being cut off. In seeding time, if weeds are large and thick, the land should be cultivated with the combine and harrowed before combining." (Secretary, Mr. H. Elliot, Karoonda.)

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

February 21st.—Present: 22 members.

HINTS ON DAIRY CATTLE MANAGEMENT.—Mr. A. Braendler read the following paper:—"Try and get the best cows procurable. A good dairy cow will not eat any more than a bad one, and, if well fed, will produce more milk than the inferior one. The Jersey cow is a good creamer. She is small and does not require so much feed as the larger breeds. The Jersey does better in a warmer and drier district than in a wet and cold locality,

The Judges at the Pruning Competitions, Mypolonga, June 4th.—Messrs. W. E. Noles and B. W. Edson of Mypolonga, and E. Leishman (District Horticultural Instructor).

where there is not much shelter. The Shorthorn and the Holstein are larger animals and consume a good deal more feed. They give more milk, but it is not so rich in cream. So far as the disposal of calves, or the cows when their milking days are over is concerned, the larger breeds always realise a better price from the butcher. Plenty of good, clean water is required, to which the cows should have free access. Sweet bone-meal should be placed in a box or trough handy for the cows to have a lick. If green feed is available all through the year, the best return from the cows will be received. In many districts this is not possible during summer, and they will have to be fed with bran or crushed oats in the chaff. Never change the feed suddenly; do this gradually, especially if grain fed, or the animals will be upset. Breed only from a well bred bull which comes from a proved milking strain on both sides, and only keep the calves from the very best cows. The calf should get the milk from the mother for the first few days after it is born. This can then be diluted with a little separated milk mixed with fresh milk for a about a week. After that put the calf on all separated milk. Always add a small quantity of calf food. Feed the calf three times a day. Provide a shelter shed for the calves to keep them warm in winter and out of the sun in hot weather.

Have a small paddock well fenced so that the calves never learn to creep. Give the calf a little bran or oats in the chaff and provide plenty of grass or hay. If well looked after, it will grow quickly and develop into a better cow than a neglected one. Do not mate heifers too young. Jerseys can be bred from six to nine months earlier than either the Shorthorn or Holstein. A well-grown Jersey can be in milk when two years old. When young farm-bred heifers come in, they are generally quiet. Tie them up on the head or put their head in a bail. Never leg rope them if it can be avoided. A good plan is to handle them quietly and milk them while you are standing and put the other hand on the rump to keep them over, and after a few milkings like this you will be able to sit down and milk them with both hands." (Secretary, Mr. C. Altmann.)

March 21st.—Present: 27 members.

CARE OF IMPLEMENTS.—The Hon. Secretary (Mr. C. Altmann) read the following paper:—"The Plough.—If one wishes to do the work properly, the plough must be in perfect order; it must run and cut straight and level, not have one body cut an inch or two deeper than its neighbor. If the plough is strained, straighten same or cause it to be straightened. Also see that the shares are of a uniform length, not one worn and perhaps four or five new ones, or *vice versa*. The seedbed must be level, and this cannot be obtained if the plough is out of order or the shares not of a uniform size. A plough out of alignment will pull harder and also leave a rough surface. See that the plough leaves a level surface and do not rely on the cultivator to do this later. A twisted plough will make the work harder for the horses and also the tractor. It may cost a little to have the plough in apple-pie order, but it pays. **Harrows.**—The tines should be of uniform length, the harrow frames sound. Well-conditioned harrows will pull hard, but they do good work in packing down the fallow. **Cultivator.**—Strained tines should be discarded; they will not leave a level seedbed. Care should also be taken to see that the tines have not slipped in the clamps. If this has happened, the clamps should be loosened and the tines set uniformly. Strained tines will not cut the weeds properly, and the share on a strained tine will wear much quicker than others. The implement should be so set that the cut of the share is almost level. **Combines and Drills.**—See that these implements are set at the proper spaces apart, not one sowing 8 in. or 9 in. apart and the other 3 in. or 4 in. This is especially noticeable on combines where the shoe is apt to slip over if it works loose. Tighten clamps after bringing in line. A good plan is to use spring washers; these hold the nut much better than an ordinary washer. **The Drills.**—The discs or hoes should be rigid and not wag. A few packing washers will, as a rule, accomplish this. See that the machines do their work right, cleaning them out after the season is over; never leave remnants of super and seed in the drill. Clean out and give a good wash with kerosene. Before starting, turn by hand by jacking up one wheel and turning same. **The Binder.**—This machine should be in good order before starting. That is best done by leaving a note in the toolbox of all defective parts when finishing harvest. Replace all worn parts before starting. Tighten up all loose bolts, and if this cannot be done, put in a new bolt or pack up with washers. Do not forget to sharpen the knife, and see that the comb is set straight to ensure free running and easy draft. It is surprising how much hay is left in the field when the knife is blunt and the comb incorrectly adjusted. Some seasons it is advisable to have a can of water in the field and pour some on to the knife to prevent same from clogging. **The Harvester.**—The same applies to the harvester in general as to the binder. With this machine, care should be taken not to blow out wheat. Some will, to get a good sample, put on a strong blast; in most cases this is not necessary—the trouble lies in the set of the machine. If a farmer studies the machine he will soon locate the trouble. **Vehicles.**—Attend to wheels on horse-drawn vehicles during the summer months. Do not use them with loose tyres; it is false economy and will only spoil the wheels. A well-tyred wheel will last indefinitely compared to a wheel with a loose tyre. Again, see that every bolt is tight; loose bolts wear the woodwork, and after a short time it will be impossible to tighten up. **Lorries.**—See that everything is and remains shipshape. It may appear costly at the first, but it will pay in the long run. **Lubrication.**—This applies to all vehicles, machinery, and implements. Do not forget to lubricate, and use the right kind of lubricant. To use oil where grease should be employed is foolish. Present-day lubrication is far ahead of what it was 10 years ago. If oilcups are fitted and the owner finds grease would be better, he can easily unscrew the oilcup and put a greasecup in its place. Always buy the best of oils. Oil little and often. Do not give an overdose and then expect the machine to run a certain time. Oil as it is required, not as you think fit. **General Care.**—Do not use fencing-wire to effect a repair; it may occasionally be necessary to use wire, but replace this with a bolt at the first opportunity. The implements will pull out of shape if one part is hung together loosely. One cannot secure as effective a joint with fencing-wire as can

be done with a bolt. After work is over, house the implements. This does not apply to ploughs, cultivators, and harrows, but drills, binders, and harvesters should not be left exposed to wind and weather. Thousands of pounds have been wasted in Australia through this practice. When housing, do not worry to clean off any old oil; good oil will not gum, but can easily be cleaned off with an old broom before starting. Do this, and then use kerosene freely on all bearings. Then before setting out use good oil freely on all bearings and there should be no trouble."

April 18th.—Present: 23 members.

EXTERMINATION OF PESTS ON THE FARM.—Mr. J. Lofthouse presented the following paper:—"The most destructive pests on the farm are rabbits, foxes, and crows. *Rabbits.*—A good plan to get rid of these pests is to insert one end of a piece of tubing in the burrow, and fasten the other end over the exhaust pipe of a motor car or motor cycle. An old bicycle tube will do. Then fill up the burrow, taking care not to allow dirt to block up the tube. Also fill in all surrounding burrows, blocking all exits. Set the engine running and the fumes will eventually choke the rabbits. Trapping is also effective, but is very slow. Foxes also have their lairs in the ground, which prove a nuisance when a team of horses has to be driven over them. Foxes pester the farmer mostly at lambing time. Skins are rather valuable, and it pays one to skin them. Poison seems to be a most effective method of dealing with this pest. Place the necessary amount of poison in the mouth of the fox's latest kill. The fox often goes back to its kill of the night before. Care should be taken not to touch the bait with the hands whilst applying poison. Another way is to drag a carcass of a dead sheep or lamb over the ground frequented by foxes. At intervals place well-secured covered rabbit-traps on the ground. Crows greatly reduce the revenue from poultry. Whilst shooting is the best way of dealing with this pest, the crow gets to know a gun, and gives it a wide berth. Place an egg on the roof of a straw stack (not frequented by fowls), place rabbit-traps covered by straw in the vicinity, and leave them. Another is to poison a carcass in a paddock, or shoot a crow and hang it up near, or on the fence of the fowl-house. This will keep crows away from the fowls." Discussing the paper, some members favored fumigation for rabbits, using sulphur and cocky chaff, it being the cheapest, and equally as effective as the exhaust fumes of a motor. A good plan, where possible, after fumigating, was to plough the burrows to a depth of about 12in. In

most cases the warren would not be re-opened. To destroy foxes, all agreed that poison was the best. Mice and sparrows made good baits. One member asked for a remedy to rid a place of rats. The Chairman said he found tar very effective. His mode of procedure was to pour tar in the holes made by the rats. He said he found they did not like the smell of tar and would soon leave the place. (Secretary, Mr. C. Altmann.)

SOUTH AND HILLS DISTRICT.

HARTLEY (Average annual rainfall, 15in. to 16in.).

Marsh 4th.—Present: 12 members.

AGRICULTURAL EXPERIMENTS.—Mr. W. Brook gave the following report of the experiment conducted on his property:—"This plot consisted of 1 acre of loamy ground, ploughed in August, 1929. It was harrowed on September 3rd, cultivated on September 30th and again on October 14th, harrowed October 23rd, cultivated January 3rd, harrowed January 7th and April 14th. The last cultivation before seeding was on April 18th. Combined April 28th, and harrowed May 3rd. Rolled with a wooden roller on May 27th, and harvested on December 18th, yielding 24bush. Expenditure—Super, $\frac{1}{2}$ cwt. 100 per cent. Cresco at 12s. cwt., 6s.; seed wheat, $1\frac{1}{2}$ bush. at 5s. bush.; ploughing, 6s.; harrowing, five times, 5s.; combining, 2s.; rolling, 1s. 6d.; harvesting 8s.; rent of land, 10s.; pickling, 3d.; rates and taxes, 8d.; bags (eight), at 9d. each, 6s.; cartage on eight bags, at 6d. per bag, 4s.; cultivating four times, at 1s. 6d. each time, 6s.; sewing bags (eight), at 1d. each, 8d.; twine, $3\frac{1}{2}$ d.; total expenses, £3 2s. 7 $\frac{1}{2}$ d."

ROAD MAKING.—The following paper was read by Mr. W. Bermingham:—"Years ago, when there was no motor traffic on the roads, the metal was cracked down to 2 $\frac{1}{2}$ in., now when it is nearly all motors we do the same thing, and wonder why the roads are always working up with loose stones lying about. This is because rubber tyres will not crush the stones as the iron tyres did. When the metal is spread on the road it should be broken down very fine, leaving nothing on top more than $\frac{1}{2}$ in. gauge. Roll it well in wet weather. Use soft limestone, if possible, and one class of stone—not some hard and some soft. Soft stone will make a smooth surface, and that is what is wanted for motor traffic. When using hard stones make them as fine as possible, and do not allow any blue or ironstone on top. If rough roads were scarified well and levelled and then broken down fine, it would be a great improvement."

LUCERNE FOR FODDER ON SMALL HOLDINGS.—At the meeting held on April 18th Mr. W. Yates read the following paper:—"Lucerne is the most useful of all green fodders. Cows, pigs, sheep, and poultry do well on it, and as it grows in summer, when all other

grasses in these districts are dry, it is all the more valuable. Nothing else gives the same return in bulk if the crop can be irrigated, and grown without water on suitable land it gives a good return. If, when planting lucerne, it is to be irrigated, do not spare the seed. If the crop is to be hand sown, a tea cup of seed mixed into half a kerosene bucket of super, sown that it works out to 12lbs. of seed to the acre, is not too much. A thick stand serves two purposes, it helps to smother weeds and keeps the lucerne from getting clumpy or tussocky. If the first cut is made when the plant is about 6in. high, it is not too soon. Be sure to make all cuts as close to the ground as possible. When irrigating one good soaking as soon as the lucerne is cut, is, in most cases, sufficient, especially if there is a good depth of soil, but if a reef of rock runs near the surface, when the plant is about 1ft. high it begins to wither and another watering is necessary to revive it. Lucerne will stand heavy dressings of manure when established. If about two bags of super to the acre are sown in early spring, the crop reaps the benefit later on, and if after the second cut (or even after each cut, if you have the manure to spare) a good layer of stable manure, or failing this, well rotted cow manure, helps to hold the water when irrigating, and also keeps the hot summer sun from baking the ground. In this dry district, where summer comes early, sow the main crop about August so that the plant gets a good start. The best result I obtained was when the lucerne was sown with barley about July. When feeding milking cows, it is necessary to cut the lucerne a while before you feed them. This does away with a good deal of the gas, and the milk does not taint." (Secretary, Mr. D. C. Harvey.)

INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

February 19th.—Present: 12 members.

LESSONS FROM 1930.—Mr. C. Grosvenor read the following paper:—At this time last year we regarded the outlook for the 1930 season as fairly good. True, with the recent sudden decline in wool values (although we entertained hopes of an early recovery of this industry) and the long period of bad to indifferent seasons, the prospects for a quick return to national prosperity were not too bright. It was against the law of averages for us to experience another dry year, and Australians generally and their leaders derived consolation from this and urged primary producers to grow more wheat and produce more from our primary industries. Since then the wave of depression which engulfed all European countries and became world-wide resulted in so much unemployment and financial stringency that all kinds of produce declined in both price and demand. Perhaps never before was the importance of our primary industries so forcibly brought home to the people of Australia. As our primary produce constitutes 95.71 per cent. of our exports and manufactured goods only 4.29 per cent., and as fresh borrowing is difficult, obviously it is only from our primary industries that we can hope to meet our payments of interest and debts and the cost of necessary imports. High prices for wheat and wool were also responsible for a general neglect by farmers of such "side lines" as dairying, pig raising, poultry keeping, fruit and vegetable growing, which were left for the few who specialised in one or more of these. To-day we find that many are anxious to get back to the more arduous work of carrying on with these "side lines" for the sake of the quick returns realised on butter, eggs, &c. The prospects for the development of the dairying industry in this State are very promising. As a result of the planting of special fodders in the Mount Lofty Ranges and in the South-East, our dairy herds should be greatly increased. In most parts of the State sheep are seen in conjunction with wheat farming. Breeders are beginning to realise that lamb raising for the export trade may be profitably undertaken, and we hear of enterprising breeders importing sires and dams from the best English studs as a nucleus of flocks which will be reared to ensure that the right type of lamb will be exported for the London market. At present the pork and lamb markets in London are very weak, but as the total cost of slaughtering, freezing, shipping, and selling pork is 3d. per pound, it may be hoped that this trade will be developed. If this is to be done (and we have had it demonstrated to us by a recent shipment of pork) pig breeders, as well as lamb raisers must pay more attention to breeding and fattening. An order for 900 pigs was completed recently. The pigs were obtained from all parts of the State, and the mixed breeding prevented the shipment of a good, even line of quality pork. There has been a marked tendency for large estates to be subdivided and smaller holdings, practising more intensive culture, are becoming more general. Producers are realising that they can produce more profitably from small areas that have been set down to pasture and subdivided into small paddocks than on large holdings whose carrying capacity is only half developed. Land values have fallen and many with a little capital are anxious to work these small holdings. Tobacco growing in many parts of the State is profitable and will, in the near future, become a great asset to the country. During 1930, 40,000bush. of Navel and Valencia oranges were exported to Canada and

met with good demand. Efforts are being made to extend the markets established in Singapore and Sourabaya. Much headway has been made in ensuring that apples and pears consigned to England and the Continent arrive in good condition. Many setbacks to the development of this trade and many difficulties have been encountered, but with the help of science many of the disadvantages due to our geographical position are being overcome. As in other citrus growing areas, we, in this district, are beginning to realise that the productivity of our orchards can be improved by the application of nitrogenous manures in the form of sulphate of ammonia and leguminous crops. Most growers of oranges in this district suffered many setbacks during the season with split fruit, hail and wind storms, and ravages of grubs. Even after the fruit was harvested and despite careful handling, it was soon evident that there would be much waste before the fruit reached the consumer. We find that this was common to all and caused by seasonal influences and the fact that growers were compelled to regulate the marketing of their fruit to meet the poor demand. Fruit and vegetables this season have been sold at prices which, to say the least, are unprofitable to the grower, and, in common with other primary producers, growers are finding that their industries are on the verge of breaking down. The question of the most suitable stock on which to propagate orange trees has long been discussed, and much research work is being done in this direction. The lemon stock here has been proved to bring the trees to maturity earlier than others, but it has many disadvantages, mainly its susceptibility to collar rot. This disease, if dealt with in its early stages, may be satisfactorily combated, but if neglected will eventually kill the affected tree. All diseased bark must be cut away from the trees and all trace of the brown-colored sap removed from the cambium layer. The exposed part should be dressed with a solution of copper sulphate or Bordeaux paste. During this season Russian wheat, grown under conditions which we are informed are tantamount to slavery, has in no small measure been responsible for the present low value of wheat, but Russia cannot continue to sell wheat at this price indefinitely. Entertaining this hope, and knowing that wool is again coming in for more demand, we may look forward to again receiving remunerative returns from our main primary industries. (Secretary, Mr. H. Lewis.)

March 19th.—Present: Seven members.

REVIEW OF THE PRIMARY INDUSTRIES.—The Hon. Secretary (Mr. H. Lewis) read the following paper:—"South Australia is essentially a primary producing State, therefore it is necessary to look to the primary industries to keep the wheels of progress in motion. The total area of agricultural and pastoral holdings in South Australia is approximately 125,000,000 acres. The total population is approximately 500,000, and of that number only 55,000 are engaged in primary production, and the mean total revenue is about £15,000,000, or an average revenue of about £33 per head of the whole population. During the past two or three years prices for primary products have steadily been on the down grade until 1930-31, when it was difficult to find a market with prices obtainable below production costs. If this continues for another year many men on the land will be applying for relief. In this district the major portion of revenue comes from sheep, although gardens and dairying considerably help to increase returns. The majority of sheep men rely chiefly on the wool cheque for revenue, but the prices obtained for the last clip have been disastrous, except for the last sale, when prices were much improved. Since the last rise there seems to be a ray of hope for better prices for wool in the future, nevertheless the lesson has been, 'do not carry all your eggs in one basket.' We must look for other avenues that can be explored to tide over this period of depression. The district is undoubtedly suitable for other side lines. A solid export trade in lamb and mutton must be established, and so give the sheep man something to rely on besides the sale of wool. Also, the cost of production must be reduced and the price improved. If this is done the present period of depression in the wool and sheep industry will pass away as it has done in the past. With increased pasture more will be cut for hay, which suggests the keeping of cows to consume it, and with dairying there is plenty of separated milk to raise pigs to avoid waste. Of the egg trade it may be said there are three paramount needs in connection with this industry—(1) Keep only the best birds, (2) market eggs of the right size, and (3) the systematic organisation of an overseas trade. According to statistics this industry returns a million pounds per year. The demand for Empire butter is very considerable. The import into the United Kingdom in 1929 was 6,250,000 cwt., the chief sources of imports were—New Zealand, 20 per cent.; Australia, 12 per cent.; Irish Free State, 9 per cent.; other Empire colonies, 1 per cent. (making 42 per cent.); and Denmark, 34 per cent.; other European countries, 19 per cent.; Argentine, 5 per cent. (making 58 per cent.), which leaves room for expansion in the Empire butter trade. There was

a rise of nearly 2,250,000ewts. in 1929 over the average of 1909-13, and out of the increase over three-quarters of it came from within the Empire, with Australia showing considerably increased output." (Secretary, Mr. H. Lewis.)

April 16th.—Present: 10 members.

SIMULTANEOUS DESTRUCTION OF FOXES AND PARROTS.—Papers by Messrs. H. Martin and H. Lush. In the case of foxes, it was decided that the month of May was the best in this district, as most rabbits were destroyed by then, and foxes would take baits more readily—such baits as parrots, fat pegs, squares of fat, liver, sardines, or old carcasses, etc. All baits should be laid well away from any thoroughfare. Foxes did a great deal of harm and caused considerable losses annually, the destruction of lambs being quoted at £40 by one member. Older residents could remember seeing the first fox reported in the district not so many years ago, and now it was not uncommon to see them in daylight. Parrots were increasing quite as rapidly as foxes and rabbits, and were more noticeable since the advent of Subterranean clover. These birds were very difficult to poison; they shelled all their grain foods, which made it practically impossible to poison them with any surface poison. They also destroyed fruit. Many residents had a small fruit garden, but very few picked any fruit off their trees this season. Rabbit destruction was a far easier work to perform, and with the present up-to-date methods of fumigation, the many makes of traps and poisons, it was possible to keep them in check. It was regrettable the prices of skins had fallen to such an extent that trappers could hardly make it pay. An interesting talk followed, and suggestions put forward as regards foxes are certainly helpful towards retailing the skin. Sardines well stirred with poison and nailed to a stump usually attracted the attention of a fox until the poison had sufficient effect on it to kill at the most 50 yards from bait. Set traps in sheep pads with weights attached and not pegged down, first of all removing all stock from the paddocks. When using parrots, it was better to keep for a week before laying them out and then bury, which appeared to make them more attractive as baits. Parrots appeared the most difficult to poison. An effective method was to mix arsenic and molasses with any grain, and a certain amount of arsenic will remain on their beaks as a result of the stickiness of the molasses. A new method put forward by one member was phosphorised grain, procured by having an airtight tin partly filled with grain, and after placing phosphorus in the tin, pour on boiling water and seal for 12 hours. One member had had good results with this method. For rabbit destruction, most members favored fumigation. If trapping and poisoning were done simultaneously a great many pests would be destroyed. It was decided to give a prize for parrot heads at per 100 as an inducement for boys to catch and destroy parrots. (Secretary, Mr. H. Lewis.)

KANGARILLA.

October 17.—Present: 12 members.

Mr. F. Smart read a paper, "The Destruction of Cape Tulip," and Congress reports were discussed. On November 5th members of the Women's and Men's Branches visited the Waite Research Institute. Sixteen members and visitors were present at the December 5th meeting, when a paper, "Increased Wool Production," was read by Mr. L. Tune.

GROWING CAULIFLOWERS.—Mr. G. Connor read the following paper at the meeting held on January 23rd:—"As in all crops, good seed is essential to success with cauliflowers. Sow in an open bed, not too thickly; an ordinary 6d. packet to two square yards. This is important; if sown too thickly they will grow with thin, weak stems and will never make good growth. The seed bed should be composed of light, loamy soil, so that when the plants are ready to plant out, they can be lifted out without damaging the roots. See that the soil of the seed bed is rich, with not too much clay. If clay is clinging to the roots, and in planting out it becomes pressed into a tight ball, it will prove fatal. Sow about the 1st March for large varieties, and I recommend Eclipse or Metropole for a good crop. Cover with a few old bags for a few days until the first leaves appear; then take them away and keep the bed watered. Keep down any weeds and thin out any thick patches. When the first rains fall, which may be in April or May, plant out into rich soil, 2ft. 6in. between the rows and not less than 2ft. between plants. A good plan is to plant in trenches, so that when they make big tops and the soil is soft with heavy rain, they can be earthed up and prevented from blowing over. When planting out, see that the seed bed has been well soaked with water the day before. Give each plant about a pint of water to start with, but on no account pug them in. Look out for grubs, green flea, and other pests. Keep them well dusted with some suitable insecticide, for if the tiny heart leaves are bitten they never recover. When they reach maturity there will be five or six great leaves there, but no heart. A very great percentage of the failures of this crop is due to the ravages of insect pests in the early stages of the life of the plant. To grow good cauliflowers, they must be kept growing from the time they show out of the ground, and to force them along is a simple matter with liquid manures. Keep a few old buckets of water

handy with a shovel full of pig, cow, and fowl manure thrown in each to dissolve for a time; also add a tablespoonful of sulphate of ammonia and the same quantity of superphosphate to each bucket. Then give each plant one pint of the liquid once a week. Keep the plot nicely cultivated, and there is no reason why they should not go along nicely and be fit for use during October. Some quick maturing varieties come on in less time; but plant early, as they will not do well if planted out in cold weather." (Secretary, Mr. T. Golder.)

LONGWOOD (Average annual rainfall, 37in. to 38in.).

February 28th.—Present: 12 members and seven visitors.

Members visited the property of Messrs. Coles and Wright, and inspected the poultry, plant, and equipment. Mrs. Coles provided tea. Mr. W. Hughes (President) presented Mr. J. B. Coles with a Life Membership Certificate of the Agricultural Bureau of South Australia. Mr. Coles has carried out the duties of Hon. Secretary for 21 years, and he has done much to further the work of the Longwood Branch. Mr. N. A. Frean gave an address on "The Possibilities of Subterranean Oil in the Hills." (Secretary, Mr. J. B. Coles.)

PORT ELLIOT (Average annual rainfall, 20.02in.).

March 24th.—Present: 14 members.

WOOL AND ITS PRODUCTS.—Mr. A. M. Fuller read part of the paper sent by the Department on this subject. The reader then said that in his opinion the severe drop from about £34 per bale to £7 for wool was not caused by over production, but by under consumption. It meant that people would rather go without new clothes than go hungry, and they were making suits, &c., last much longer than previously. Gold was at present held in United States of America, France, and Argentine, and unless redistribution was effected they could not hope for prosperity. The majority of the gold, as it was held by only three countries, restricted credit and reduced the purchasing power of the whole world. Mr. H. Welch thought that synthetic wool was one of the causes of the drop in prices, and Mr. Keen said that one of the reasons for the manufacture of this article was the high price of the real thing. Mr. Crompton said that wearing apparel had altered a good deal during the last few years, especially in the amount of wool, much more silk being used. Messrs. Smith, Deplidge, and White also spoke. (Secretary, Mr. A. Lowe.)

April 18th.—Present: 18 members.

SUBTERRANEAN CLOVER AND FAT LAMBS.—Under the heading, "My Experiences in the Port Elliot District and what they have led to," the following paper was read by Mr. P. James:—"Since taking up land in this district I have seen the highest prices received for wool ever experienced in the history of the State, but no great time elapsed before a very severe slump took place. Prior to being a landholder in the Port Elliot district, I occupied a property at Onkaparinga, and from my experiences there I was convinced that this district was one admirably suited to the growing of Subterranean clover, although I received little encouragement from my neighbors. Onkaparinga district 30 years ago was in a very similar condition to what Inman Valley was when I arrived. Thirty years ago the farmers of Onkaparinga depended a good deal on hay-growing, but had got to the stage when their crops were rather light; but since the district has grown heavy crops of Subterranean clover, it is marvellous what heavy crops of hay they can grow now, though it is a very limited area that is sown. Also, after a paddock had been cropped, it used to take very many years to get it grassed again, but where land had a good crop of clover previous to cultivation, it was very soon a good grass paddock again, and it will do the same for us. For instance, if we grow a crop of peas for lambs, we will have a good clover paddock again almost immediately, especially if following peas we grow barley. Onkaparinga has about an average of 6in. per year of rain more than Inman Valley, but the soil is not so clayey. Having seen what clover and super had done for the former district, I said it would do the same for this part. Both districts are also red and blue gum country. Having decided to grow clover, my next problem was to find the cheapest method of establishing it on the land already grassed with native grasses. My first experience was practically a failure—broadcasting seed on grass land. The second year I mixed seed with super and just scratched it in with a hoe-drill, and that was a great success, and I have been on that method ever since. Six years ago without super and clover the lambs reared were miserable, stunted little creatures, so I stopped breeding and went in for dry sheep until last season, when I changed over to about 300 ewes, with the result that though the first lambs were not dropped until August 8th, by January 1st 85 per cent. of the wether lambs had been sold for fats, and it was a pleasure to show them to any one that called. They were out of Merino and Crossbred ewes by Corriedale rams. When I bred the miserable lambs six years ago a fat lamb was worth about 30s.; to-day about 10s. to 12s. I am quoting prices from November to January. Wool was about 36d.; to-day 1s. That is the revenue

side. Expenditure:—Land tax has more than doubled, car tax has nearly doubled, district council rates nearly doubled, and railway freight and income tax have risen. Are we doing the best with our land, which is carrying a good growth of clover, by keeping sheep and selling wool for 1s. a lb., and fat lambs for 10s. to 12s., or should we change over to dairying. Land that is suitable for fat lambs to a certain extent is very suitable for dairying." Mr. H. Welch said that Mr. James had made a wonderful difference in his farm since he purchased it. Mr. A. Fuller was of the opinion that the writer had some of the finest lambs in the district. As regards clover pasture, &c., he thought that the land should be broken up every seven or eight years, to improve the feed. Mr. White said they should not rely entirely on Subterranean clover, as it was an unbalanced ration, but add mixed grasses, such as the various ryes, &c. It was better to have a mixed farm than have only sheep. Mr. J. Crompton informed members that he had seen Subterranean clover established at "Stoneyfell" over 30 years ago. Talking on the present state of the markets, Mr. H. L. Smith said that the cost of production must come back so that the farmer could afford to use super. A discussion followed on "Pork," and Mr. James said that with the present low prices for store pigs, wheat, etc., pork could still be produced at a profit, in spite of the low prices obtained. Mr. Smith said that about 13 per cent. to 14 per cent. of the money received went in cartage and commission charges. (Secretary, Mr. A. Lowe.)

STRATHALBYN (Average annual rainfall, 19.43in.).

March 31st.—Present: 18 members.

The Ashbourne Branch gave the programme for the evening, the speakers being:—Mr. Horwood, "Licks for Sheep"; Mr. H. Pitt, "The Value of Scientific Research in Agriculture and Kindred Pursuits;" and Mr. C. Pitt, "Some Aspects of Potato Culture." Mr. Horwood in his remarks said there were quite a number of licks suitable for sheep, but many were too expensive for general use. Top-dressing of pasture was very beneficial to grazing for sheep. It was advisable to use a small quantity of molasses in all licks. The mixture was:—100lbs. ground rock phosphate, 100lbs. salt, and 6lbs. molasses. The speaker also touched on methods of feeding. Mr. H. Pitt spoke on the cost of running a farm, and said that experiments and demonstrations were being carried out to improve and lessen the cost of production, therefore the practical work done at Roseworthy College and Waite Research Institute could not be judged by a financial balance-sheet. The speaker read an article showing what was being done in New Zealand by feeding stock with ensilage. He also advocated the analyses of soils to find the plant foods in which they were deficient. Mr. C. Pitt tabled fine samples of potatoes taken from his property at Ashbourne. He said the most important thing in growing potatoes was selection of seed; it should be strong and healthy, and a change of seed was necessary. Treatment of seed:—Place the seed on wire-netting and do not be afraid of the sun doing harm. Sow plenty of fertiliser. The plants must have food, and if a good harvest is to be secured the proper foods for the plants must be there to obtain it. (Secretary, Mr. F. Allison.)

CROWN LANDS.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

AGRICULTURAL PUBLICATIONS.

The following publications have been issued and are available for distribution at prices mentioned :—
"First Aid to the Horse," by F. E. Place, B.V.Sc., M.R.C.V.S., &c. ; price, 3s. ; posted, 3s. 2d.
Journal of the Department of Agriculture, 5s. per annum in advance ; 1s. per single copy to residents in South Australia. Other places, 10s. per annum ; single copies, 2s. each.
 The bulletins and leaflets may be obtained by sending a 1d. stamp for postage.
 All communications must be addressed—Ed., "Journal of Agriculture," Box 901E, G.P.O., Adelaide.

THE AGRICULTURAL BUREAU.—Particulars of this Organization, of which every farmer should be a member, can be had on application to the Department.

CLOVER TROUBLES

in PASTURES.

Mr. R. Crowe, Export Superintendent of the Department of Agriculture, Victoria, emphasises the bad effect of excess clover on the keeping qualities of milk, cream, and butter in an article on "Butter Factory Management," extracts of which are published in the *Victorian Journal of Agriculture* for August, 1930. For those dairymen and lamb raisers who encounter bloat and kidney disease in stock and "clover taint" in milk it is essential to obtain more grass in proportion to clover in their pastures. Autumn is the best time to rectify the trouble, and the following system should prove satisfactory :

- 1.—Autumn Harrowing and Reseeding with Wimmera rye grass in low rainfall areas and perennial rye and cocksfoot under moister conditions.
- 2.—Application of Sulphate of Ammonia. $1\frac{1}{2}$ cwt. per acre in April or May after soil has been well saturated by Autumn rains.
- 3.—July Application of Sulphate of Ammonia 1 to $1\frac{1}{2}$ cwt. per acre. In addition to improving the grass-clover balance the use of sulphate of ammonia will provide valuable grass growth during the Winter and early Spring months.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences of Branches of the Agricultural Bureau are being arranged as follows:—

Murray Mallee (West), at Karoonda, Tuesday, August 11th. (Secretary, Mr. B. Harrold.)

Pinnaroo Lines, at Pinnaroo, Thursday, August 13th. (Secretary, Mr. H. L. Badman.)

Southern, at Langhorne's Creek, Thursday, August 20th. (Secretary, Mr. P. H. Nurse.)

Hills, at Mount Pleasant, Thursday, August 27th. (Secretary, Mr. D. Stow Smith.)

The above Conferences will commence at 10.30 a.m. in each case. Papers and questions for Conferences should be sent to the General Secretary, Agricultural Bureau, about a fortnight prior to the respective dates mentioned.

Forty-Second Annual Congress.

The Forty-Second Annual Congress of the Agricultural Bureau will be held in the Way Hall, Franklin Street, on September 14th, 15th, and 16th.

His Excellency the Governor has intimated that he will be pleased to deliver the opening address on September 14th at 8 p.m. At this session the Minister of Agriculture (Hon. S. B. Whitford, M.L.C.), and the Chairman of the Advisory Board of Agriculture will also address the delegates. At a recent meeting of the Agenda Committee, it was decided to request Dr. A. E. V. Richardson (Director of Waite Agricultural Research Institute), Messrs. W. R. Birks (Principal Roseworthy Agricultural College), H. Showell (Renmark), H. B. Barlow (Chief Dairy Instructor), and C. F. Anderson (Pottery Expert) to give special addresses at different sessions.

Branches have been asked to submit papers, resolutions, questions, and subjects for discussion not later than August 7th, when the Congress Committee will meet to consider the agenda. A draft copy of the agenda will then be submitted to Branches to give members an opportunity of discussing the items with delegates.

Bureau members who may be in Adelaide during Show Week are reminded that the Congress is not held exclusively for those who are appointed as delegates. The meetings are open to all members, who may also bring friends with them. When dealing with resolutions, &c., only delegates will be allowed to vote.

Delegates and members attending the opening session on Monday night are requested to take their seats at 7.45 p.m.

A visit will be made to the Waite Agricultural Research Institute on the morning of Thursday, September 17th, when visitors will have an opportunity of viewing the experimental work upon which Dr. Richardson will address the Congress on the Wednesday night.

Special sessions will be held for delegates and members of Women's Branches.

Imperial Fruit Show.

The Imperial Fruit Show will be held this year at the City Exhibition Hall, Manchester, from October 30th until November 7th.

Now in its eleventh year, the Imperial Fruit Show is not only a commercial fruit show, but also a popular public exhibition. Its purpose is not only to promote better methods of cultivation, packing, grading, and marketing of Home and Empire grown fruits—fresh, canned and dried—but also to show the English public the quality and variety produced within the Empire boundaries.

The show is held in two sections, one in the spring and the other in the autumn. The spring section, specially arranged to meet seasonal conditions in South Africa, Australia, and New Zealand, has just concluded, whereat Australia secured the major number of awards in both the culinary and dessert apple classes. The points awarded for the culinary and dessert apples in the two main classes will be compared and judged with the Empire apples from the northern hemisphere exhibited at Manchester in October next.

The various sections in which Dominion growers may compete are:—

Section V.—Overseas Section (Citrus)—Open to growers, packing stations, associations of growers and exporters in any part of the British Empire (five classes).

Section VII.—Canned Produce Section—Open to canners in any part of the British Empire, but all produce shown must have been grown and canned in the British Empire (22 classes).

Section VIII.—Dried Fruit Section—Open to producers and packers in any part of the British Empire. All fruit must have been grown in the British Empire (10 classes).

Special provision has also been made for a Honey Section, which has been introduced for the first time this year. This section is composed of two divisions, one of which is open to the United Kingdom only, and the other, which is confined to exhibits from the Dominions and Colonies. In the latter division competitors may enter for the following classes, viz.:—

(a) One market case of honey in tins.

(b) Three jars of granulated honey, gross weight to approximate 3lbs.

(c) Three jars of clear honey, gross weight to approximate 3lbs.

Entry fees are 5s. for each exhibit in Class (a) and 2s. for each exhibit in Classes (b) and (c). Prizes of £3 for first, £2 for second, and £1 for third will be awarded in each class.

Fruitgrowers and others interested may obtain entry forms and copy of the schedule containing full information regarding the classes and other particulars from the Secretary, Department of Markets, 527, Collins Street, Melbourne.

Grape Skins for Fertilising Material.

The Greenock Branch of the Agricultural Bureau submitted samples of fresh and decayed grape skins and asked for information as to the fertilising value for (1) orchards and vineyards, (2) cereal crops, and (3) pastures. Prof. A. J. Perkins, Director of Agriculture, in reply, says:—

The samples were submitted to Dr. Hargreaves, Director of Chemistry, for analyses, with the following results:—

| | Grape Skins. | | Farmyard Manure. | |
|---------------------------|---------------------|-----------------------|---------------------|----------------------|
| | Fresh. Per cent. | Decayed. Per cent. | Fresh. Per cent. | Rotted. Per cent. |
| Moisture | 19.8 | 17.1 | 75 | 75 |
| Nitrogen | 1.29 | 1.05 | 0.39 | 0.50 |
| Lime | 0.55 | 0.98 | 0.49 | 0.70 |
| Phosphoric acid | 0.44 | 0.27 | 0.18 | 0.26 |
| Potash | 2.19 | 1.56 | 0.45 | 0.63 |

Relative to the above analyses, I wish to state that everything depends on the accuracy with which the samples were taken, and it seems to me that from the point of view of a normal sample, the percentage of moisture is very low, and it must be realised that any remarks that may be made in reference to this particular sample are naturally influenced by the low moisture content indicated. Should the bulk have a higher proportion of moisture, the statements made would no longer hold good.

You will notice that side by side with the figures for grape skins I have shown normal analysis of both fresh and rotted farmyard manure. I have done this because it is essential that a manure like grape skins should be compared with one of this type. The

main difference between the two, that is to say, between grape skins and farmyard manure, appears to be the high proportion of moisture present in the latter, and on this basis farmyard manure is less rich in mineral constituents than grape skins.

I notice your statement to the effect that the orchards and vineyards of your district are well supplied with humus, resulting from green grass which is annually ploughed under. In this connection I am personally inclined to doubt the value of this statement. You perhaps overlook the fact that well-tilled orchards and vineyards are practically subject to a treatment which corresponds very largely to continuous bare fallow, and one of the results of well-tilled bare fallow is to break up and destroy the organic matter, the mineral constituents of which become then available as plant food. It is impossible, therefore, that a treatment of this kind going on from year to year can have any other result than the gradual wasting of whatever organic matter may have been originally present in the soil, and the winter burial of the few weeds that may grow in these orchards and vineyards will be insufficient to make good this loss. Hence, in my opinion, the dressing of grape skins, like a dressing of farmyard manure, has one important connection—that of bringing new organic matter to the soil. As to the mineral constituents, they can, of course, be compared to those present in common artificial manures. At the same time, it should be carefully borne in mind that, whereas the mineral constituents of artificial manures are in an easily available form to plants, the same constituents in grape skins cannot become available until brought under the influence of a succession of soil bacteria, and, although eventually the plants will get the full benefit of them, it is only after a succession of years. The figures that I am about to give, therefore, should be borne in mind in this particular connection.

Nitrogen.—In the fresh skins we see 1.29 per cent. of nitrogen and in the decayed 1.05 per cent. If we assume a dressing of grape skins corresponding to that usually given of farmyard manure, namely, 10 tons per acre, this would mean that the amount of nitrogen present in the 10 tons of fresh grape skins would correspond to that present in nearly 13 cwt. of sulphate of ammonia, and in 10 tons of decayed skins to that present in 10½ cwt. of sulphate of ammonia. Please remember, however, that if the moisture present is higher than that given for the sample these figures would be correspondingly lower.

Lime.—The fresh skins are shown to contain 0.55 per cent. and the decayed skins 0.98 per cent. These figures mean that the lime present in 10 tons of fresh skins would be roughly 1 cwt. and that present in the decayed skins roughly 2 cwt.

Phosphoric Acid.—The fresh skins are said to contain 0.44 per cent. phosphoric acid and the decayed skins 0.27 per cent. These figures mean that 10 tons of fresh skins would contain phosphoric acid corresponding to that present in 4½ cwt. of 45 per cent. superphosphate, and 10 tons of decayed skins to that present in about 2½ cwt. of 45 per cent. superphosphate.

Potash.—Fresh skins are said to contain 2.19 per cent. potash and the decayed skins 1.56 per cent. These figures mean that 10 tons of fresh skins would contain potash corresponding to 8½ cwt. of commercial sulphate of potash and the decayed skins at 6½ cwt. of commercial sulphate of potash.

I should, perhaps, have stated earlier that naturally the composition of decayed skins in comparison with the fresh skins will depend a good deal on the length of time the processes of decay have been at work and the manner in which the skins may have been kept, that is to say, whether exposed to the weather or not.

Finally, it is asked that a statement should be given of the value of those skins for orchards and vineyards, for cereals, and for pastures. Personally, I am of the opinion that the most useful position in which they could be placed would be on orchards and vineyards. Under our conditions of climate, they would have comparatively little value for cereals, chiefly because of the slow progress involved in the availability of the mineral constituents. Young cereal plants require to find within their immediate reach all the mineral food necessary to their early development, and among these chiefly

Illustration shows a Fordson operating a heavy scoop on a Victorian dam construction job. One-man scoops are also available.

THE FORD MOTOR COMPANY
LONDON AND
SYDNEY
AUSTRALIA

The NEW FORDSON TRACTOR

Power for every purpose.. at lowest cost

The New Fordson Tractor offers an abundance of economical power for a multitude of industrial, farming or transportation tasks . . . either as a mobile or stationery unit. On the farm when field work slackens, the sturdy Fordson supplies the means to build dams and drains, haul heavy loads, fill silos, operate threshers, chaffcutters, circular saws, and all types of labour saving equipment. The task of cutting production costs becomes simple when you employ a Fordson. Labour charges are reduced to a minimum, and you perform twice the work in half the time at a fraction of the cost of old fashioned horse-team methods.

Your nearest Ford Dealer can prove clearly that the New Fordson *will* reduce your farming costs. Ask him for your copy of the Fordson Equipment catalogue *The Standard Fordson : £220 at nearest Ford Works, Sales Tax Extra Ford Motor Company of Australia Pty. Ltd.*

phosphoric acid, lime, and nitrates, and even if this material were ploughed under at fallowing time, it is doubtful whether it would have reached the stage of decay to make it of much use to young growing cereals.

However, if land to be sown to cereals were lacking in organic matter, a dressing of these skins would be useful if applied at fallowing time.

I think that if top dressed for pastures their value would be very largely wasted.

"Economic Aspects of Mixed Farming in the Murray Valley, 1930."

HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. GEO. QUINN, Chief Horticultural Instructor.]

Fruiting of the Granny Smith Apple.

"Can the Department of Agriculture supply me with any information concerning the fruiting of the Granny Smith apple?" ("T. H. G.," Beaconsfield). Replying to the question, Mr. Geo. Quinn (Chief Horticultural Instructor), says whilst the Granny Smith is being much more favored than formerly, nearly all of the trees met with in our commercially conducted orchards have barely reached the fruiting stage.

Our experience in the State Experiment Orchard at Blackwood has been that the mature type trees in our apple collection has fruited quite well. It, of course, is growing amongst a hillside block, each tree of which consists of a different variety, so we do not know which sort may be influencing it in the direction of cross-pollination.

In another portion of the Orchard in a Bitter Pit stock trial block we worked over a good number of mature trees of Shockley to Granny Smith about five to six years ago—grafting on to the stumped main arms. These trees are in good land and have grown tremendously. They are mostly on Spy or other blight-proof roots, and some have an intervening stem of another sort—Rome Beauty or Dunn's worked on the Spy, etc. These combinations do not seem to have retarded their growth or fruitfulness in any way. These trees have cropped quite well also, but they grow in a block in each short row of which there is a mixture of sorts consisting of Cleopatra, Jonathan, Spitzenburg, Baldwin, and Shockley, so that here again the question of cross-pollination is befogged.

In regard to pruning, we have treated the old type tree to only moderate pruning, and the young, vigorous growth from the grafts, after the first couple of seasons when reshaping the trees, was uppermost in our minds, we have given the trees considerable latitude. Whilst the leading shoots have been topped, the laterals have only been thinned out and rarely shortened at all.

This latter procedure is, I think, accountable for the good crops collected thus far.

DAIRYING INQUIRIES.

[Reply supplied by Mr. H. B. BARLOW, Chief Dairy Instructor.]

Formalin-pickled Barley for Pigs.

"*Would the feeding of formalin-pickled barley be injurious to pigs?*" (Wasleys Agricultural Bureau). Reply—"Provided the barley is not just freshly pickled, and has dried out, it is not injurious to pigs."

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

"*W. H. C.,*" Parrakie, has Jersey cow 7 years old unable to get in calf, and (2) horse, when not feeding, stands with head down nearly touching the ground and moves neck from side to side. Replies—(1) *Barren Cow*.—In view of the length of time the animal has gone "empty," despite repeated attempts to breed her, it is very doubtful if you will succeed in getting her in calf again now. The only treatment you can attempt is to douche the vaginal passages out once daily for a fortnight (starting immediately after the next time she is in season) with a gallon of lukewarm Condyl's solution (strength, $\frac{1}{2}$ teaspoonful crystals to 1 gall. water). Then for a further week, give daily douches of 1 gall. lukewarm salt solution (strength, 1 teaspoonful salt to each pint of water). Then when the cow comes "in season" again, give a final douching with a solution of baking soda (same strength as the salt solution). This douche should be given half hour prior to service by the bull. (2) *Horse*.—There is nothing very "diagnostic" in the symptoms you describe. Have her teeth examined, there may be a diseased tooth that requires attention. A drench of raw linseed oil, $1\frac{1}{2}$ pints; turpentine, 4 tablespoonfuls, should be given after 16-24 hours starvation, and the animal subsequently given a tablespoonful of liquor arsenicalis in damped feed night and morning for a fortnight.

"*T. O. M.,*" Borrika, reports mare served end of last September, joints very stiff, and during past two weeks milk has been flowing from the udder. Reply—The mare should not require any special treatment beyond seeing to it that she gets regular exercise and is not allowed to get into too fat condition. She can, with distinct advantage, be kept in moderate slow work, even right up to within a day or two of foaling. This will provide the first of the two above requirements, and will also, to

DAIRY FARMERS!**MILK PRODUCTION**

**CAN DEFINITELY AND PROFITABLY BE INCREASED BY FEEDING
MEGGITT'S LINSEED MEAL.**

Meggitt's is a highly concentrated food, rich in essential milk producing and body building protein and conditioning linseed oil in the correct proportions.

It is obtainable from any Dairy Produce Factory, Grain or Chaff Merchant, or direct from—

ELDER, SMITH, & CO., LIMITED,
SELLING AGENTS IN SOUTH AUSTRALIA.

some extent, help to obviate the latter. Her food ration should be regulated so that suitable condition is maintained, and the provision of a certain proportion of green feed in it is essential, more especially towards the latter stages of her pregnancy. Just before and for a short time after foaling her feed ration should be somewhat curtailed and be of a laxative nature.

"H. A. L.," *Wirrelyerna*, asks are ewes subject to mammitis. Reply—Yes. The udders of all breeding ewes should be examined, and any showing signs of mammitis should be culled.

"C. F. Z.," *Wallala*, reports horse with piece of chaff in the eye. Reply—Treatment will depend upon how long the husk had been in the eye. If seen early, irrigation by the squirting in of a warm solution of boracic acid may dislodge it sufficiently to be able to remove with a piece of cotton wool tied around the end of a pen handle. If it has been in position for a day or so and a white membrane commences to form around the husk, a solution of cocaine should be obtained from a doctor and instilled into the eye and left for five minutes. Then the animal will open the eye and allow the husk to be removed with a small pair of forceps, or swab of cotton wool. For two or three days after removal bathe the eye with a strong solution of boracic acid and place a guard made of clean bagging over the eye to keep out the light.

"L. B. S.," *Halidon*, reports aged pony which periodically breaks out in lumps, which do not discharge, but disappear later, leaving a dirty white scaly appearance. Reply—The cause is probably dietetic, especially if pony is kept in fat condition. When feeding dry food, cut down the grain as much as possible, substitute bran and give one tablespoonful of baking soda in feed night and morning. Twice a week give about $\frac{1}{2}$ pint of raw linseed oil mixed in the chaff to keep bowels in a laxative state.

"G. E. S.," *Cowell*, has (1) sheep licking burnt up straw; (2) question of procuring laudanum when a chemist is 100 miles away. Replies—(1) Sheep licking burnt straw would possibly be a sign of a mineral deficiency, and it is most likely to be phosphorus, calcium, sodium chloride, or a deficiency in all three. Such deficiencies can be made good by giving any of the following mineral supplements in the form of a lick, which can be placed out in kerosene tins cut longways:—1. Ground rock phosphate, common salt, equal parts—mix well. 2. Superphosphate, common salt, equal parts—mix well. (2) This question was referred to Messrs. F. H. Faulding & Co., Ltd., wholesale chemists, Adelaide, who advised that provided there is no doctor or chemist within 20 miles of him, a storekeeper can obtain supplies. If you have a doctor within 20 miles of the local store you could probably obtain supplies from him when required, but if the local storekeeper is 20 miles from a doctor, he can obtain the medicament from Messrs. Faulding & Co., Ltd., Adelaide.

"A. J. O.," *Ceduna*, has mare in fat condition with an irritation affecting the legs. Reply—The symptoms described suggest irritation by mites, which infest grasses, &c., at this time of the year. Try the following treatment:—Apply a mixture of raw linseed oil (1 pint) and lysol (2 tablespoonfuls) to the legs, rubbing it on with a brush after shaking mixture well. Repeat two or three times. If feeding hay of chaff give 1 tablespoonful of baking soda mixed with the feed twice a day for a week. Reduce mare's condition and give green feed, if available.

"Mrs. A. C. T.," *Cherry Gardens*, asks treatment of a cow with boils on the udder. Reply—Wash the udder thoroughly with soap and warm water and dry. Then clip to remove all long hair on under part of udder and around site of the boils. Paint the boils with the following solution after every milking:—Take tincture of iodine, Friar's balsam, glycerine, of each 2ozs.; mix and shake well before applying. The abscesses, when opened or when they break, should be syringed out with a solution of washing soda (1 tablespoonful to the pint of water) to get rid of all discharge, and a plug of cotton wool soaked in the iodine solution inserted once or twice to get rid of the discharge remaining.

"C. H. P.," Brinkley, reports draught mare with leg swollen from hock to fetlock. Reply—The condition is known as "lymphangitis," and is brought about by various causes. It often affects horses with a sluggish temperament, or horses on a rich diet and doing very little work, or horses coming in from the paddock and put on to hard feed, and it often tends to become chronic. *Treatment.*—Give the horse 8ozs. of Glaubers salts dissolved in a pint of water as a drench, apply hot fomentations of water to the affected leg, give plenty of exercise, reduce the grain in the ration (substituting bran for it) and give plenty of green feed. Smaller doses of Glauber salts (1oz.) should be given in the dry feed daily for six days.

"H. B. S.," Wilmington, has heifer suffering acutely from "Redwater." Reply—This condition in the case mentioned is probably due to a deficiency in the diet, and similar cases occurred in other parts of the State when drought conditions were prevailing. You do not give any particulars as to the bodily condition of the heifer or her previous history. The following treatment is recommended. Give the following drench:—Epsom salts, 1lb.; ginger, 2ozs.; treacle, $\frac{1}{2}$ lb.; water, 2 pints. Bring her in from the paddock and feed on chaff, bran, and crushed oats twice a day in addition to any grass available. Mix in the feed night and morning 1 $\frac{1}{2}$ ozs. of the following mixture:—Superphosphate, 1lb.; common salt, 1lb.; powdered nux vomica, 4ozs.; powdered ammonium carbonate, 4ozs. Mix and make mixture. If weather is cold, keep heifer rugged.

"H. B. C.," Narridy, requests cure for itch on legs of horses. Reply—This complaint is due to the irritation caused by mites, which are present in pastures, &c., at this time of the year. The application of oily dressings containing a little lysol, creosote, once or twice is generally effective. Mineral oils should not be used, as they often cause irritation. Any comparatively cheap vegetable oil is recommended, such as raw linseed or cotton seed oil mixed in the proportion of 1 pint with 2 tablespoonfuls of lysol.

## PRESENT AND FUTURE ECONOMIC POSITION OF FARMERS.

[By ARTHUR J. PERKINS, Director of Agriculture.]

*(Address at the Conference of Upper North Branches of the Agricultural Bureau  
at Willowie, July 15th, 1931.)*

### INTRODUCTORY.

I have been asked to address you on the position of the farmer—present and future—particularly in relation to personal finance. It is fairly obvious that such a request must have been prompted by the difficulties that have beset you as a result of the calamitous fall in the price of Wheat, coming, unfortunately, in immediate succession to an unusually prolonged period of unfavorable seasons. On the latter point at least, let me congratulate you on the very fine prospects of the current season, and express the hope that we have now, for a period of years at all events, definitely broken with droughts and all their distressing consequences.

The more recent cause of your discomforts—the fall in price of Wheat—cannot, however, be dismissed so readily. This unfortunate decline would appear to have been brought about by two main economic facts, namely:—

- (1) World-wide Financial depression which, by curtailing the purchasing power of consumers, has led to a fall in prices of all commodities alike; and
- (2) World over-production of Wheat dating back to 1926.

With the latter point I dealt fully in my address to Congress last year, and I shall therefore content myself with reminding you that, relatively to pre-war World consumption, over-production of Wheat since 1926 has been at the mean annual rate of approximately 500 million Bushels per annum. Now, normally over-production of a commodity of the universality of Wheat will always right itself fairly readily if left to itself. Over-production in such circumstances involves low prices, and low prices lead to increased consumption on the one hand, and on the other tend to drive into other lines of activity those who find the production of the commodity concerned least profitable; and this combination leads usually to reduced production coupled with slowly improving prices until a state of approximate equilibrium is reached. Unfortunately, when the fact of World Wheat over-production began to be realised the solution of the trouble was not left to the play of normal economic factors, but frantic efforts were made to stem the tide of gradually falling prices by withholding vast quantities of wheat from the markets of the world. In so far as the *temporary* maintenance of abnormally inflated post-war prices was concerned these efforts were no doubt successful, but, eventually, to the Wheat-growers of the World these efforts did great disservice by holding in check World Wheat consumption at a time when the purchasing powers of its chief consumers were at a very low ebb, and driving the latter into the use of Rye and other cheaper surrogates, which at some cost must now be systematically displaced. But from the very outset the end was well in sight; this artificial bolstering up of prices cast a discreet veil over realities, and for the time being did nothing towards checking over-production. Eventually, however, after a few ineffective struggles, stored Wheat had to be released, and led to the spectacular drop in prices that we know of, the like of which has not been paralleled in the last hundred years.

There is perhaps some compensation for wallowing at the bottom of a trough. The position may not be very comfortable, but there is consolation in the knowledge that when in the fulness of time a change does set in, it can be in one direction only, and that is upwards, and the only anxiety is whether length of time may not get the better of native endurance. Of one thing, we may in the meanwhile feel positive, and that

is that the continuance of abnormally low prices is steadily, if slowly, working in the farmer's favor. It is, on the one hand, promoting increased World consumption of Wheat, and on the other, the gradual disappearance of unprofitable Wheat areas, and eventually such a combination can have but one effect, namely, progressively improving Wheat prices. If, in this connection, I may be allowed a purely personal expression of opinion—and you must take it for no more than it is worth—I shall say that we have good reason to anticipate better Wheat prices in 1932 than those current in 1931, but that the extent of this improvement in prices will be governed by the World financial position rather than by the available net World supplies of exportable Wheat.

#### WHEAT AND THE SOUTH AUSTRALIAN FARMER.

All this is by way of introduction to an examination of the position of the South Australian farmer, both in the present and in the future. He is, as you know, very firmly rivetted to Wheat as the main line of his activities. The whole of his farming practices have been directed towards the maximum production of Wheat that the seasons and his means permitted of; and when Live Stock operations have been associated with Wheat, it has usually been with an eye to improved production of the latter, and even when a scrub block has been taken up it is usually with the assistance of Wheat that it has been economically reclaimed for whatever ultimate purpose it may have been required. Personally, I can see no alternative to Wheat in South Australia, particularly in its Northern Agricultural Areas, except complete reversion to Sheep, which would be tantamount to putting back the clock of progress in a State essentially built upon agricultural development. No, others may and will withdraw partially or wholly from Wheat, but South Australians simply cannot do so.

In this connection I shall probably be told that at current prices farmers are receiving for Wheat considerably less than costs of production, and in such circumstances how can they be expected to continue growing Wheat? Because there is no alternative; because low prices and poor seasons will be succeeded by better ones; and finally because the tenacity and grit of the farmer is such that he will not give up his farm until he is forcibly driven off it.

Whilst I am prepared to admit to the personal opinion that present-day prices determined upon a strict accountancy basis do not and cannot pay costs of production of Wheat on the average farm, nevertheless, I recognise the difficulty of strict proof in the matter. I could no doubt put forward towards that end the data collected at Turretfield Demonstration Farm over the past nine years, but these data unfortunately do not correspond to those of the average South Australian Farm, and could not be accepted as adequate evidence. On this farm there is a paid Manager, and all Labor incurred is met by Cash payments, whereas on the average farm the owner is working Manager, and the place of hired labor is taken very largely by unpaid family Labor. But if in order to meet the position we were to place an artificial value on the owner's work and on that of his family, absence of adequate daily records would usually render impossible a fair distribution of the value of this Labor between Wheat and other farm activities, such as Sheep, Cows, other Crops, &c., and the same difficulty would apply to some extent to the distribution of the value of team work and of the wear and tear of implements and tools.

But even if notwithstanding these difficulties it were possible to arrive at an acceptable determination of costs of production on a single farm and in a single season this would not take us very far: we should still have between 12,000 and 13,000 Wheatgrowers on each one of whose farms costs per Bushel would vary not only one with the other, but also on one and the same farm from field to field and from season to season. In other words, quality of land, Capital investments, strictly local seasonal conditions of the year, prevalence of disease or accidents, managerial and technical skill, other personal

idiosyncrasies, and in some measure "luck," all would in varying degree have their say in the determination of mean yields per acre in any one year, and as to whether corresponding mean costs per acre would be relatively high or relatively low; and as to whether the farmer would be adequately rewarded for his labor by Wheat prices current at the time.

#### A NORTHERN FARMER'S ESTIMATE OF COSTS OF PRODUCTION OF WHEAT.

And since we cannot hope to discuss the question from the standpoint of a true State mean, I propose falling back upon second best and availing myself of a very fair estimate of the position which was submitted by Mr. W. Crawford, of Mannanarie, at the 1926 Conference of Mid-Northern Branches, and which was published subsequently in full in the May, 1926, number of the *Journal of Agriculture*.

Mr. Crawford told us that his statement had been based upon 10 years personal experience of an 800 acre farm with an 18in. rainfall. This farm carried annually 350 acres of Wheat sown upon Bare Fallow, of which 80 acres were cut for Hay. The Wheat had averaged 24bush. to the acre over ten years. A flock of 150 Ewes had been associated with Cropping operations.

From data supplied by Mr. Crawford the Capital invested in his 800 acre farm admits of the following summarised statement:—

|                            | Total. |        | Per Acre. |    |    |    | Per Cent. |    |
|----------------------------|--------|--------|-----------|----|----|----|-----------|----|
|                            | £      | £      | £         | s. | d. | £  | s.        | d. |
| Land and Improvements ..   | —      | 9,600  | —         | —  | —  | 12 | 0         | 0  |
| Implements and Tools ....  | 763    | —      | 0         | 19 | 1  | —  | 6         | 4  |
| Farm Vehicles .....        | 180    | —      | 0         | 4  | 6  | —  | 1         | 5  |
| Personal Vehicles .....    | 220    | —      | 0         | 5  | 6  | —  | 1         | 9  |
| Harness .....              | 116    | —      | 0         | 2  | 11 | —  | 1         | 0  |
| Stationary Engine .....    | 75     | —      | 0         | 1  | 11 | —  | 0         | 6  |
| Working Horses .....       | 260    | —      | 0         | 6  | 6  | —  | 2         | 2  |
| Farming Plant .....        | —      | 1,614  | —         | —  | —  | 2  | 0         | 5  |
| Sheep .....                | —      | 225    | —         | —  | —  | 0  | 5         | 8  |
| Cash requirements .....    | —      | 400    | —         | —  | —  | 0  | 10        | 0  |
| Total Capital .....        | —      | 11,839 | —         | —  | —  | 14 | 16        | 1  |
| Interest on Capital at 6 % | —      | 710    | —         | —  | —  | 0  | 17        | 9  |

It will be observed that in the above statement the value of Land and Improvements—£9,600—represents more than four-fifths of the Capital invested, and corresponds to yearly interest dues of £576, or 14s. 5d. per acre per annum. This sum which must be met yearly from Farm revenues, equals the value of 1,536 bags of Wheat at 2s. 6d. a bushel; or of 1,280 bags at 3s.; or again, of 1,097 bags at 3s. 6d. Mr. Crawford told us that for a period of ten years his mean returns had been at the rate of eight bags to the acre from 270 acres reaped for Wheat; hence, with Wheat at 2s. 6d. a bushel, for every 100 bags reaped 71 bags would have been required to meet interest dues on Land and Improvement alone; with Wheat at 3s. a bushel 59 bags; and with Wheat at 3s. 6d. a Bushel 51 Bags. Nor should it be forgotten that additional provision would have to be made for interest dues on Stock and Plant. Hence, it would appear to be overwhelmingly clear that farmers who purchase high price land are treading upon very thin ice, and that no such purchases should be effected unless the farmer is amply satisfied that they represent a reasonable business proposition. Moreover, in this connection, it is not the boom prices of abnormal years that should be the determining factors, but the mean prices of the immediately preceding quarter of a century.

It can, of course, be objected that Mr. Crawford's farm, although perhaps typical of his immediate district, is after all not typical of the North as a whole. For purposes of comparison, therefore, I have shown overleaf corresponding figures for the mean of 23 Northern No-Tractor Farms collected for me by your District Agricultural Instructor, Mr. E. L. Orchard.

*Mean Capital Invested in 23 Northern Areas.*

Mean Area = 869 acres. Mean Area Cropped = 275 acres.

|                                | Total.   |              | Per Acre. |          |              | Per Cent. |              |
|--------------------------------|----------|--------------|-----------|----------|--------------|-----------|--------------|
|                                | £        | £            | £         | s.       | d.           | £         | s. d.        |
| Land and Improvements . . .    | —        | 6,737        | —         | 7        | 15 1         | —         | 81-3         |
| Implements and Tools . . .     | 346      | —            | 0         | 8        | 0            | —         | 4-2          |
| Farm Vehicles . . . . .        | 77       | —            | 0         | 1        | 9            | —         | 0-9          |
| Personal Vehicles . . . . .    | 169      | —            | 0         | 3        | 11           | —         | 2-0          |
| Harness . . . . .              | 38       | —            | 0         | 0        | 10           | —         | 0-5          |
| Stationary Engine . . . . .    | 44       | —            | 0         | 1        | 0            | —         | 0-5          |
| Working Horses . . . . .       | 217      | —            | 0         | 5        | 0            | —         | 2-6          |
| <b>Farming Plant . . . . .</b> | <b>—</b> | <b>891</b>   | <b>—</b>  | <b>1</b> | <b>0 6</b>   | <b>—</b>  | <b>10-7</b>  |
| Sheep . . . . .                | 174      | —            | 0         | 4        | 0            | —         | 2-1          |
| Cattle . . . . .               | 66       | —            | 0         | 1        | 6            | —         | 0-8          |
| Pigs . . . . .                 | 8        | —            | 0         | 0        | 2            | —         | 0-1          |
| Poultry . . . . .              | 17       | —            | 0         | 0        | 5            | —         | 0-2          |
| <b>Revenue Livestock . . .</b> | <b>—</b> | <b>265</b>   | <b>—</b>  | <b>0</b> | <b>6 1</b>   | <b>—</b>  | <b>3-2</b>   |
| <b>Cash Requirements . .</b>   | <b>—</b> | <b>400</b>   | <b>—</b>  | <b>0</b> | <b>9 2</b>   | <b>—</b>  | <b>4-8</b>   |
| <b>Total Capital . . . .</b>   | <b>—</b> | <b>8,293</b> | <b>—</b>  | <b>9</b> | <b>10 10</b> | <b>—</b>  | <b>100-0</b> |
| Interest on capital, at 6% .   | —        | £498         | —         | 0        | 11 5         | —         | —            |

It will be observed that whilst the area of the average Northern Farm—869 acres—is slightly greater—8.6 per cent.—than that of Mr. Crawford's farm, the mean area under crop—275 acres—is appreciably lower—21.4 per cent. Similarly, the value of Land and Improvements per acre—£7 15s. 1d.—is 35.4 per cent. lower; the value of Stock and Plant per acre—£1 6s. 7d.—is 42.3 per cent. lower; and the value of total interest on Capital—£498—is approximately 30 per cent. lower. It should be added that for purposes of comparison I have adopted Mr. Crawford's figure of £400 to meet current cash outgoings.

The position of the average farm would therefore appear to be more favorable than that of Mr. Crawford's farm, but for the fact that smaller cropping areas, coupled with reduced mean yields per acre, would tend to neutralise the advantage of reduced interest charges.

Interest charges on Land and Improvements would be equivalent to the value of 1,011 Bags of Wheat at 2s. 6d. a Bushel; or to 4.4 Bags per acre from 230 acres reaped for grain. Corresponding figures with Wheat at 3s. would be 898 Bags and 3.9 Bags respectively; and with Wheat at 3s. 6d., 770 Bags and 3.3 Bags respectively.

Finally, I have summarised below the data upon which Mr. Crawford determined his mean costs of growing a 24-Bushel crop of Wheat.

|                                                  | Mr. Crawford. |             | Turretfield.                                 |
|--------------------------------------------------|---------------|-------------|----------------------------------------------|
|                                                  | Total.        | Per Bushel. | Mean of Eight Seasons<br>for 19½ bush. Crop. |
|                                                  | £             | s. d.       | s. d.                                        |
| Interest on Capital . . . . .                    | 710           |             |                                              |
| Depreciation on Capital . . . . .                | 102           |             |                                              |
| Purchase of Material . . . . .                   | 230           |             |                                              |
| Management and Labor . . . . .                   | 560           |             |                                              |
| All other costs . . . . .                        | 437           |             |                                              |
| <b>Gross total costs . . . . .</b>               | <b>2,039</b>  |             |                                              |
| <b>Less Revenue from Hay and Sheep . . . . .</b> | <b>570</b>    |             |                                              |
| <b>Net costs . . . . .</b>                       | <b>1,469</b>  | <b>4 6</b>  | <b>4 10</b>                                  |

From this table it will be observed that Mr. Crawford has endeavored to get round the difficulty of discriminating between costs incurred on behalf of Wheat, on the one hand, and those incurred on behalf of Hay and Sheep, on the other. He has assumed that Wheat-growing is preponderantly his major farm operation, and that Hay and Sheep do no more than contribute towards its success. In the circumstances, all farming costs have been charged against Wheat, and Revenue from Hay and Sheep have been deducted from Gross Costs, the difference being taken to represent Net Costs of growing Wheat. Such a practice is probably justifiable, in the absence of adequate data; but it must not be overlooked that it does not take into account that both Hay and Sheep taken by themselves might, according to circumstances, prove profitable or unprofitable, and as such introduce an artificial element in net cost per bushel of Wheat, namely, 4s. 6d.

I shall offer one other criticism on Mr. Crawford's statement, and that is that the allowance for Depreciation on Capital items—£102—is, in my opinion, inadequate; £240 would probably be nearer the mark, and if adopted would have the effect of approximately raising Mr. Crawford's Net Costs to the Turretfield mean figure of 4s. 10d. per Bushel.

It will be recalled that Mr. Crawford's statement is based upon a farm on which Land and Improvements were assessed at £12 an acre. I have already referred to the danger of high-priced land: let me point out here that if the land in question had been valued at £6 instead of £12, Mr. Crawford's costs per Bushel would have been reduced to 3s. 8d., a figure which we may have to accept as a normal mean in the immediate future.

#### THE PRESENT POSITION OF FARMERS.

Now, whilst neither Mr. Crawford's estimate of costs of production nor actual costs at the Turretfield Demonstration Farm can be accepted as typical of the State as a whole, bitter experience, if not accounts, have driven home to us the fact that 2s. 6d. a bushel cannot possibly cover normal costs of production of Wheat anywhere in South Australia. In this connection, although somewhat loath to do so, I shall state that in the past when times were more normal, I have not hesitated to insist that farmers, who were engaged in the great national undertaking of growing Wheat, were at the very least entitled to a return of their costs of production, if not to something better in the shape of Net Profits. To-day, unfortunately, conditions are no longer normal; not wheat-growers only, but the great majority of primary producers of the Commonwealth is not realising costs of production from prices offering; even highly protected manufacturers find themselves in corresponding difficulties. Nor is the plight of importers and professional men generally appreciably better; but, worst of all, an army of unemployed is tramping the streets of our Cities in dejected idleness instead of contributing to the development of the Commonwealth. Our mistakes as a community are no doubt partly to blame for this distressing state of affairs; but the main cause—World-wide depression and poverty, following on the wastage of World War—cannot surely be laid at our doors. In the circumstances I feel confident that you will all agree with me that the present is not the time to haggle over costs of production, but rather to thank God that unlike hundreds of thousands of their fellow-citizens, primary producers are at least in continuous employment, however unremunerative such employment may for the moment happen to be; and to glory in the knowledge that in a time of grave national emergency the ultimate rehabilitation of the affairs of the community is dependent very largely upon your grit, intelligence, and untiring efforts. But I have no need to labor this point; the Wheat-growers of South Australia have already shown in most effective manner that they appreciate their responsibilities in this direction. This State is indeed to be congratulated on the fact that notwithstanding their great personal difficulties, its Wheat-growers have not hesitated to place under Wheat in 1931 an area almost equal to that seeded in 1930, in which year a new State record for areas sown was established.

In this connection it seems to me well that we should remind ourselves that farming, no more than engineering, teaching, and other relatively ill-paid avocations, is not usually taken up for the sake of the profits it may promise, but rather as a means of earning a modest livelihood in congenial occupation. You are farmers, I take it, because you love farming, notwithstanding the hardships it occasionally entails; you love the scent of the turning sod, the willing work of a well-balanced team, the tender green of the newly sprouted grain; and if you rise early and retire early, it is what Nature intended. Man should labor by the light of the Sun; it is wild beasts only that roam about at night, seeking whom they might devour. There are very few of you who would exchange farming for any other occupation, notwithstanding the illusive glamor of cities, with their mansions and slums, their noisy crowds and lonely souls, their occasional "plums" and more frequent unemployment. In the City, when costs of production are not adequately balanced by selling prices, the manufacturer has no alternative but to shut up shop. Does the same hold good in the country? I think not; and the thousands of farmers that are clinging to the land to-day is clear proof of it. Let us look into this matter more closely.

In Mr. Crawford's estimate total yearly expenditure was represented by £2,039 and total yearly receipts by £1,380 only, if we assume Wheat to realise 2s. 6d. a bushel only; this represents a loss of £659 on the year's transactions, which proportionately would be sufficient to cripple any manufacturer. But in these total costs of £2,039 are included two items, namely, Interest and Depreciation, £822, and Management and Labor £560, neither of which involve actual payments, unless the farmer is in debt, or runs his farm on hired labor. We shall agree that in principle the farmer is entitled to expect the value of these items from his farm returns; but if in any particular year, as a result of seasonal difficulties or low prices, farm returns are insufficient to provide for Interest and Depreciation, his means of livelihood are not necessarily in jeopardy, unless indeed he is in debt to an unreasonable extent. If now we deduct the value of Interest and Depreciation—£822—from total costs—£2,039—we shall get £1,217, representing all other costs, and including £560 for remuneration of Management and Labor. And since total receipts with Wheat at 2s. 6d. have been set down as £1,380, the farmer and his family, assuming no hired labor to be employed, would be in receipt of £723, but no provision would have been made for interest and depreciation. If we assume that there were a mortgage on the property to the extent of half its value, i.e., £4,800, this at 6½ per cent., would involve interest charges of £312 per annum, which on deduction would still leave to the farmer and his family £411 for the immediate expenses of the year. Mr. Crawford, on the other hand, makes no reference to possible returns from Cows and Poultry; when the latter are added to other farm activities they can without great cost be made responsible for additional farm revenue to the extent of £100 to £150 per annum.

In conclusion, I shall say relatively to the present position of farmers that whilst at present prices they are certainly not receiving adequate returns for their efforts and for the Capital they are compelled to sink in their business, they have the satisfaction of knowing that they are not alone in this plight; and that those among them who have husbanded their resources in the past, and have not over-capitalised their farms on borrowed money, should be able to pull through, at the expense, it is true, of temporary reduction in their standard of living. A farmer has the advantage of a rent-free roof over his head; with ingenuity he can almost make his farm support him in foodstuffs; and facing, as we hope, an excellent season, he has good reason for optimism, notwithstanding unsatisfactory current prices for rural produce. There are, of course, some who are carrying a load of debt out of proportion to the producing value of their holdings, and to these I can offer nothing beyond the sincerest sympathy in their troubles.

## THE FUTURE.

It has been suggested that after dealing with the present position of farmers, I should don the mantle of a prophet and discuss the prospects of the immediate future. But, apart from the fact that I have probably already trespassed upon your patience unduly, it has always seemed to me that it is not in times of adversity that we should concern ourselves much with the future, except, perhaps, to keep up our courage. If, on the other hand, in the days of our prosperity we were to give some thought to the lean years that always lay ahead of us, we should, when the latter come, meet them on more equal terms. But lest I be accused of running away from the question I am prepared to say a few concluding words on the future.

I have already expressed the opinion that Wheat prices are likely to improve slightly in 1932; and although we cannot hope for a return of abnormal post-war prices, there is every reason to believe that succeeding years will gradually raise Wheat to normal value. I have indicated below, in ten-year periods, the mean prices of Wheat during the past 69 years:—

|                   | <i>s.</i> | <i>d.</i> |          | <i>s.</i>       | <i>d.</i> |
|-------------------|-----------|-----------|----------|-----------------|-----------|
| 1861-70 . . . .   | 5         | 11        | a bushel | 1901-10 . . . . | 3 10      |
| 1871-80 . . . .   | 5         | 3         | a bushel | 1911-20 . . . . | 5 5       |
| 1881-90 . . . .   | 4         | 4         | a bushel | 1921-29 . . . . | 5 2       |
| 1891-1900 . . . . | 3         | 9         | a bushel |                 |           |

It can be added that during this period of 69 years, in five seasons only was the mean 12-month price of Wheat below 3*s.* a Bushel, namely:—

|                | <i>s.</i> | <i>d.</i> |          | <i>s.</i>         | <i>d.</i> |
|----------------|-----------|-----------|----------|-------------------|-----------|
| 1893-4 . . . . | 2         | 3         | a bushel | 1899-1900 . . . . | 2 9       |
| 1894-5 . . . . | 2         | 9         | a bushel | 1900-01 . . . .   | 2 10      |
| 1898-9 . . . . | 2         | 9         | a bushel |                   |           |

A contemplation of these figures, coupled with the knowledge that economic factors are quietly working in our favor, should lead to the belief that we are well on the way to the 3*s.* mark, whilst we hope that 4*s.* a bushel will be attained in no distant future. In the meanwhile Farmers must carry on to the best of their abilities and means, and take such consolation as they may from the thought that nothing but mismanagement or extreme ill-luck can put them out of employment.

There is another factor which might be made to contribute to the end we have in view, if only Primary Producers of the Commonwealth could be induced to present a common front in the matter of Commonwealth fiscal policy. A reduction in costs of production would be equivalent to an increase in price per bushel. Our present relatively high costs are in part the natural consequence of 30 years of Protection policy, adopted deliberately with a view to rendering Australia self-supporting in the matter of important secondary industries. The object aimed at has probably been attained by now, but at the expense of primary production, which, like all these secondary industries, will soon find itself unable to compete on the markets of the World, because of unnaturally inflated Costs of Production. The remedy is for Primary Producers of the Commonwealth to unite and demand a purely revenue-earning tariff. The secondary industries have had 30 years to consolidate their positions, and if with the assistance of a 10 per cent. *ad valorem* tariff and long distance freight they are unable to hold their own on the home market, it is time that they sent in their checks.

If the fight to reduce tariffs fails there is an alternative which has been adopted in other primary industries with an exportable surplus, such as the Dried Fruit industry, and that is, the fixing of a special price for the home market, which for Wheat could

be secured by means of a Sales Tax or an Excise Duty on Flour used for home consumption, the proceeds of such tax or excise duty to be divided equitably among all Wheat Growers of the Commonwealth *pro rata* to the amount of Wheat delivered by each grower to market. However much one might dislike these artificial props to production, they represent, unfortunately, the only alternative in the artificial atmosphere of a country run mad on protection.

I anticipate, too, that in the future there will be few farmers who think themselves above taking regular advantage of the profits that can always be derived from Cows and Poultry: both in their way yield exportable products, and as such are important national assets. It is possible, too, that pork, if not green bacon, may yet come into its own as a commodity of profitable export, but of this I am less confident. Apart from exceptional conditions of locality or climate, I am assuming that the farm of the future that is without its well-bred Fat Lamb Flock, its sleek milkers, and its busy hens, will be as much an anomaly as a farm without horses at the present moment. This intensive association of Live Stock with cropping operations is not likely to reduce appreciably present-day areas sown to Wheat; it will, however, assist to maintain our soils in a high state of fertility. Nor in the days of their prosperity will future farmers neglect to make ample provision for the Live Stock requirements of succeeding lean years.

At your request and on your behalf I have tried to look at both the present and the future with eyes of hope; and if I have been able to do so, it is because I am not without experience of the South Australian Farmer, and that I have the utmost confidence in his ability to pull not only himself, but others as well, out of tight corners. I feel that your faces are set towards the dawn of better things: go on and prosper, but do not forget that evening shadows follow the dawn.

## RECENT DECLINE IN THE DAIRYING INDUSTRY: ITS CAUSES AND REMEDY.

ADDRESS TO S.A. BUTTER AND CHEESE FACTORY MANAGERS AND  
SECRETARIES' ASSOCIATION.

[By ARTHUR J. PERKINS, Director of Agriculture.]

I should put first and foremost among the causes of decline that have overtaken the Dairying Industry within recent years the fact that we have not yet developed as a people what for want of a better term I shall call the Dairying "sense." By this I mean that we are in the habit of taking up Dairying when needs must, but hasten to drop it again as soon as we can see our way to some more congenial form of occupation. We are apt to magnify its so-called "drudgery"—I have heard it called White Slavery—and we are often blind to the great interest that should attach to the efficient handling of a herd of high grade milkers. I recognise that an unwilling Dairyman will never make an efficient one, and I shall suggest in the sequel that the first step towards building up a great and permanently profitable industry should be an organised attempt to interest the rising generation in Dairying.

The second and perhaps more obvious cause of the decline has been the abnormally high post-war prices of both Wheat and Wool. These prices led very generally to the replacement of Cows by Sheep, whilst many farmers preferred to concentrate on the profits which could at the time be derived from Wheat to the exclusion of all Livestock operations.

A third cause was the high prices offering for meat on the local markets. A fat cow came to be considered too valuable to be kept on the farm, and usually found its way to the butcher's. In addition, both bull and heifer calves were indiscriminately sent to market at the first opportunity.

The cumulative result of all these destructive forces has been that in the course of six successive seasons South Australia lost over one-third of her Milch Cows, a fact which to-day is hampering us very considerably in our attempts to extend our Dairying operations.

I have suggested that in order to overcome our national dislike of Dairying we should endeavor to open the unprejudiced eyes of Youth to the great interest that attaches to Dairying as an occupation. In the present critical state of our affairs, when the City can no longer offer careers to the rising generation, and the cry of a return to the land is making itself felt in our midst, would appear to rest our opportunity. In the early nineties, and in somewhat similar conditions, the same cry, as some of you may recollect, led to the establishment of Village Settlements on the banks of the Murray; whilst some of our more imaginative citizens sought greener fields in distant Paraguay. This attempt at settlement of untrained and inexperienced City dwellers in the wilderness probably fulfilled its main if hidden purpose of giving temporary employment to some of the unemployed; but from the standpoint of permanent land settlement it was eventually an unmitigated failure. Eventually, too, after variegated careers, the Paraguayan adventurers crept back to our drabber conditions. And to-day, when similar schemes are more or less in the air, it would be well that we bore in mind the lessons to be derived from the experiments of the nineties.

I have, however, no intention of suggesting the expansion of Dairying as a temporary measure for coping with present-day unemployment. Indirectly, no doubt, it will contribute in some measure to the reduction of unemployment: but we cannot hope to build up effectively a great industry calculated to help the State out of its financial difficulties; if we attack the problem from the angle of purely temporary expediency. We all recognise that one of the main causes of our troubles is the calamitous fall in World prices of our exportable commodities, and the consequent reduction in our

national income: the obvious remedy has been suggested that we should strain every nerve to increase production in proportion to the decline in prices. When, however, the general level of prices is considerably below actual costs of production the whole burden of rehabilitating the community is actually thrown upon producers, and it is to be feared that in present circumstances our producers of Wheat and Wool—our main exportable commodities—are doing all that circumstances permit them to do. In order, therefore, to increase the value of our exportable commodities there remains to be considered whether important portions of our territory could not be put to more profitable use from the standpoint of exports. In this connection, and in present circumstances, I know of one and one only form of rural activity likely to give us the desired results, and that is the intensive practice of Dairying, associated in some degree with Poultry-Keeping. Although far from munificent, World prices for Butter and Cheese are sufficient to maintain the careful dairyman on the land; there appears even to be some hope of the profitable export of fresh pork, if not of bacon; eggs, too, in the shell or in the state of pulp, represent valuable export commodities. I am of the opinion, therefore, that the economic situation offers no insuperable obstacle to the expansion of dairying in our midst, could we but take to it in the right spirit. Dairying saved Victoria in the past; it is one of the chief sources of wealth of our neighbor, New Zealand, and of many other progressive countries of the world: it is not yet too late for us to take up the running. Towards this end, wherever conditions of climate and soil warrant it, land should be subdivided into smaller units, and in many instances Sheep will have to give way to more profitable Cows. In our Hills' Districts and the South-East alone there are enormous areas that should gradually be converted into Dairy Farms. The top-dressing of pastures, coupled with the introduction of improved grasses and clovers, has rendered successful dairying possible in these districts on quite moderate areas. The more general use of Ensilage, on the other hand, would open the way to successful Dairying, in districts of less abundant rainfall. Finally, general farmers are coming to realise their mistake in discarding Cows: there are over 12,000 of them, and they could easily be responsible for 100,000 Cows.

I realise, however, that in these times of financial stringency and low prices for rural products considerable responsibility rests upon those who take upon themselves the task of recommending expansion of any one of our rural industries. Such expansion, although eventually of advantage to the State, may not prove profitable to the individual producers. I propose, therefore, from the data available to me, to examine to what extent Dairying should prove profitable in the hands of the average careful Dairyman.

At this stage I must state frankly that in these difficult times it is not from the standpoint of "Net Profits" that this question can be discussed: and this notwithstanding the fact that I am persuaded that even in these times such Profits are not altogether beyond the reach of progressive dairymen. But in many cases, as in most rural occupations to-day, there will be no net profits; they may even be replaced by losses on a strict accountancy basis; and yet the producer will continue on his holding by accepting a temporary reduction in his standard of living: it is the sacrifice he makes for the common good, receiving in return continuous employment in congenial occupation. Hence, the only possible method of approaching the subject is to ascertain whether under good management the average Dairyman is likely to realise a Labor Income sufficiently great to maintain himself and his family on the land, and not whether he can anticipate adequate interest on Capital invested. And this, unfortunately, is the position of most primary producers at the present time.

In this connection I shall take advantage of a recent financial Survey of Dairying under Irrigation Conditions carried out by the Federal Development Department, over which the Honorable J. Gunn presides. The survey in question concerned the irrigated areas of New South Wales, Victoria, and South Australia for the season ending the 30th June, 1929, i.e., at a time when the value of Dairy products was approximately 10 per cent. higher than at present. For the sake of simplicity, however, I shall confine my quotations to results registered for the Murray Swamps and the Goulburn Valley respectively.

The Survey shows that the mean Labor Income of 34 Goulburn Valley Dairymen on farms 76.3 acres in mean area averaged £250 10s. per annum, and on the Murray Swamps for 36 Dairymen on farms averaging 37 acres, £246 10s. When we bear in mind that these Labor Incomes represent the differences between Mean Gross Receipts and Mean Expenditure incurred apart from the value of the personal Labor of the farmers concerned; that in this expenditure are included not only actual out-of-pocket expenses, but in addition the value of the assistance which the farmers received from members of their families, together with interest and depreciation on Capital, apart from that on the farmers' dwelling houses; when we take all this into consideration we shall probably agree that these mean Labor Incomes, although far from princely, should suffice in these times to keep the competent dairyman and his family on the land.

I have already expressed the opinion that the progressive Dairyman should be able to do even better than that; and the Survey of the Development Department goes far to prove my contention, as the data in the following Table will show:—

TABLE I.—*Mean Data concerning Irrigated Dairy Farms in order of Labor Incomes earned in 1929.*

| No. of Farms.    | Labor Incomes. |             | Mean Areas. | Mean No. of Cows. | Receipts.   |             | Expendi-<br>• ture. |
|------------------|----------------|-------------|-------------|-------------------|-------------|-------------|---------------------|
| Nos.             | Range.<br>£    | Means.<br>£ | Acres.      | Nos.              | Dairy.<br>£ | Total.<br>£ | £                   |
| GOULBURN VALLEY. |                |             |             |                   |             |             |                     |
| 10               | Under £150     | 72.8        | 83.7        | 17.0              | 459.6       | 624.5       | 552.1               |
| 7                | 150-249        | 207.3       | 72.3        | 18.6              | 492.9       | 706.2       | 498.9               |
| 8                | 250-349        | 279.1       | 63.0        | 18.8              | 595.0       | 762.5       | 483.4               |
| 9                | 350 and over   | 456.6       | 82.8        | 22.3              | 1,006.3     | 1,212.5     | 756.1               |
| 34               | Means          | 250.5       | 76.3        | 19.2              | 643.0       | 829.4       | 579.0               |
| MURRAY SWAMPS.   |                |             |             |                   |             |             |                     |
| 7                | Under £100     | 46.4        | 34.8        | 20.2              | 496.1       | 524.1       | 477.6               |
| 11               | 100-199        | 137.5       | 36.8        | 23.9              | 635.0       | 704.9       | 567.6               |
| 6                | 200-299        | 257.8       | 40.8        | 24.5              | 685.9       | 740.2       | 482.4               |
| 7                | 300-399        | 360.6       | 42.4        | 29.1              | 926.7       | 970.4       | 609.8               |
| 5                | 400 and over   | 593.0       | 42.6        | 26.9              | 905.7       | 1,100.4     | 507.2               |
| 36               | Means          | 246.5       | 37.0        | 24.7              | 710.8       | 782.2       | 535.7               |

You will observe that in Table I. the 34 Goulburn Valley Dairymen have been split up into four groups with Labor Incomes of progressively improving values; and that similarly the 36 Murray Swamp Dairymen have been distributed among five approximately corresponding groups. For the purpose of the comparison I have in mind I shall make no mention of the intermediate groups, but simply call your attention to the extreme groups, that is to say, the groups comprising farmers with lowest and highest mean Labor Incomes respectively. In this connection you will notice in the first place that there is little to choose between the mean areas of the Goulburn Valley Farms in either group, but that the mean number of Cows milked is greater in the group with high Labor Incomes than in the one with low Labor Incomes; that mean total receipts of Farmers with high Labor Incomes were nearly double those of Farmers with low Labor Incomes, whereas their expenses apart from Personal Labor were not 50 per cent. greater than those of Farmers with low Labor Incomes. The net result is that whilst 10 Farmers earned mean Labor Incomes of £72 16s. only, nine others, working under almost identical conditions, earned mean Labor Incomes of £456 12s., *ie.*, approximately 6½ times greater. That the main cause of these striking differences is one of personal management is emphasised by the fact that the mean Labor Income per Cow is £4 5s. 8d. only in one case and £20 9s. 6d. in the other.

I shall not worry you with an analysis of the position of the Murray Swamp Dairymen beyond drawing attention to the fact that the Mean Labor Income of seven Dairymen was £46 8s. only, or £2 6s. 4d. per Cow, whilst that of five others working under very similar conditions was £593 or £22 8s. 11d. per Cow.

# 3 Harrows in One for the Price of One

The Whakatane Harrow is an all-purpose implement designed in such a way that three exceedingly efficient working surfaces can be secured from the one set of harrows. On the one side a long time cultivation is provided for, on the other, when drawn one way, the harrow becomes a first-class tripod, and when drawn the other way, as shown in the accompanying illustrations, a manure-spreading, seed-covering harrow, which many skilled farmers and agricultural experts claim as being the finest manure spreading effect so far made possible with harrows. The Whakatane is designed to treat all classes of country and to suit different types of farming—wheat areas, dairying and mixed farming—being particularly suited for the renovating of pastures and the preparation of seed beds. Its principle of "three harrows in one" gives it an extremely wide scope of usefulness and renders it superior to any of its kind.

These figures, I believe, confirm my impression that given careful management and adequate business acumen it is possible to make more out of Dairying than falls usually to the lot of the average man. They may also be said to stress the great difficulty of striking an accurate mean for the costs of production of agricultural products in any given district, let alone for a whole State offering an infinite variety of natural and economic conditions. It might probably be said of the Dairymen we have had under consideration that if it cost the most successful 4d. a gallon—to take an altogether random figure—to produce milk, it probably cost the least successful in excess of 2s.

It may be objected that the figures quoted above have reference to Dairying under irrigation conditions only, and that corresponding Labor Incomes would not necessarily be earned under non-irrigated conditions. Unfortunately, I have no corresponding figures for purposes of comparison; but as a matter of personal impression I shall state that Mean Labor Incomes of equal value to those of irrigated areas can be earned on non-irrigated areas, provided that the Dairyman is placed on suitable country and that he has not purchased his land at inflated values, and that possible lower mean milk yields are usually set off by lower costs of production. In the circumstances I feel justified in maintaining that of the various rural occupations practised in our midst to-day Dairying is among the very few, if it does not stand alone, that can safely be recommended for almost unlimited expansion.

You may perhaps be inclined to think that my contention that the future expansion of the industry is contingent upon our ability to interest the rising generation in Dairying, savors somewhat of an attempt to put off the evil day. This, however, is very far from being the case. I am perfectly willing to welcome into the fold—or shall we say the cow byre—every seasoned veteran of parts who hears the call and is prepared to stand by his cows to the end of his days. On the other hand, at the present moment cows are not locally available at acceptable prices and in numbers adequate to any important degree of expansion; and I need not remind you that a mere change in ownership of cows because ruling prices happen to be high does not imply any appreciable degree of expansion in the industry. It is for this reason that I suggest that willing, unprejudiced youth should be taken in hand to-day, at a time when normal avenues of employment are closed to it, and that during the necessary interval of training we should prepare the way for its ultimate settlement in profitable and we may hope congenial occupation.

But what in the meanwhile should be done? The suggestions that follow involve in some degree questions of Government policy, and must not therefore be taken to have more value than that of my own personal opinion:—

1. An immediate call should be made for suitable youths willing to take up training as Dairymen with a view to ultimate settlement on the land. The Roseworthy Agricultural College could absorb some of them, even if as an emergency measure they had to be housed under canvas. Others could be apprenticed to approved dairymen; and the balance, if any, might be allotted to special relief farms that could be brought into being for the purpose.

2. Special steps should be taken to see that suitable land were made available for Dairying at an early date, and preferably not later than two years hence. What these steps should be would probably involve political action, and I must therefore leave their determination to others.

3. We should do our utmost to check the slaughter of heifer calves and to see that they ultimately take their place in the depleted ranks of our milkers. Towards this end we should make full use of moral suasion, and if necessary of legislative action. I do not suppose that we could reasonably prevent an owner from slaughtering a calf on his own premises; but we could surely do so at the public slaughter yards to which the majority would tend to gravitate. Provision, too, should be made for taking over at a moderate fixed price the calves of those who are unwilling or unable to rear them, on the understanding that the owner, if he so desires, should retain an option over them at a specified age.

4. It must be assumed that the type of settlement I have in mind would imply temporary State assistance to some of the settlers; but if undertaken, it is to be hoped that our recent experiences in the matter of Soldier Settlement will effectively block the way to settlement on the basis of 100 per cent. borrowed money. I suggest that no settler should have less than £500 in Cash, or its free equivalent in Stock and Plant.

5. The land would probably be allotted on a Covenant to purchase agreement; and as the object in view would be the settlement of Dairymen, and not of axemen, I suggest that if the land be not cleared, it should be cleared by contract prior to allotment, and the cost of clearing be added to the original cost of the land. Had this policy been adopted in the settlement of the Mallee many a pioneer settler would not have been ruined in the process of preparing the way for another.

6. If possible, steps should be taken towards securing suitable Milch Cows from the neighboring States, and to dispose of them to Dairymen at cost price.

7. Apart from the settlement of what might be termed full blooded Dairymen, every encouragement and assistance should be given to Wheat Farmers to keep Cows. An effectively handled herd of 6 to 12 Cows would probably constitute the safest form of insurance against intermittent need for State assistance in years of drought.

8. We should take early steps towards giving the Industry from which we expect so much effective protection against the Margarine menace.

We are probably all agreed that the State stands in need of increased Dairy output, but thus far we have considered this need from the standpoint of increase in numbers of both Dairymen and Cows only. Obviously, however, increased total output can be secured within certain limits by increasing the mean output of existing herds. And let me say here that we are just as much in need of increased output per Cow as of increased State output—one should go with the other. Indeed, the former presents the inestimable advantage of reducing the costs of the Dairyman and of putting him in a better position to meet successfully a period of falling prices. The time allotted to me does not permit of my dealing in detail with this question; moreover, there does not appear to be any particular need for me to do so, since I notice from the agenda that my friend, Mr. Barlow, proposes rehabilitating the Industry, and I have no doubt that increased production per Cow will receive his special attention. I shall therefore content myself with bringing under your notice what have been the mean milk yields per Cow of the various States over a period of five years, closing in 1928-1929:—

TABLE II.—*Showing Mean Milk Yields per Cow, 1924-1929.*

| South Australia .....   | 336               | 317               | 329               | 332               | 337               | 330                             |
| Western Australia ..... | 218               | 239               | 244               | 261               | 277               | 248                             |
| Tasmania .....          | 311               | 266               | 305               | 336               | 362               | 315                             |
| Commonwealth.....       | 363               | 320               | 319               | 349               | 352               | 341                             |

It will be observed that relatively to those of the other States our milkers have not shown up to any great disadvantage during this period of five years, notwithstanding the fact that we were suffering from the effects of drought over the greater part of the time. Nevertheless, we can aim at more than an average of 330 gallons per Cow. Victoria attained to 450 gallons in 1928-1929, and there is no reason why, with improvement in our Dairy Stock, and particularly with better feeding methods, this figure should not be the general average for the Commonwealth.

I am afraid that this address, which has been rather hurriedly prepared, does not give a very adequate statement of what in my mind I had intended to say. In the main I wished to express my belief in the Dairying Industry as one of the levers that is destined to lift the State out of its present uncomfortable position; and that we should do all in our power to forward its development and to encourage the younger generation to assist us in the process.

## CITRUS EXPERIMENTS AT THE STATE EXPERIMENTAL ORCHARD, BERRI.

[By GEO. QUINN, Chief Horticultural Instructor, and N. S. FOTHERINGHAM, Manager Berri Experimental Orchard.]

### FERTILISER TESTS.

In 1920 a series of tests with fertilisers was inaugurated at the above Orchard. Although the primary object was to endeavor to ascertain what, in this regard, constituted the limiting factor or factors governing the successful development of healthy citrus trees and the production of profitable crops therefrom, it was hoped, at the same time, by using each fertiliser in increasing quantities upon adjacent rows of trees in the plot devoted to that particular fertiliser, to obtain some information as to the most profitable quantity to apply to the citrus soils of the Murray Valley.

Four plots of trees were selected to be annually dressed with superphosphate, bonedust, sulphate of ammonia, and sulphate of potash respectively. In between the two plots receiving the phosphatic dressings, two others, each consisting of one row only, were dressed with a "complete fertiliser" composed of superphosphate, sulphate of ammonia, and sulphate of potash in one instance, and in the other, bonedust equivalent in phosphoric acid replaced the superphosphate.

As the land is naturally rich in lime carbonate, these combinations may be deemed to represent what are popularly termed "complete fertilisers," whilst the four first-named fertilisers represented dressings of water soluble phosphoric acid, water insoluble phosphoric acid, readily available nitrogen and potash respectively.

The only citrus trees of a fruit-bearing age in the Orchard in 1920 consisted of Washington Navel oranges which had been procured by the Irrigation Department from various commercial nurseries and planted in 1912. The exact species of citrus used as stocks for these trees and the origin of the buds worked upon them were, and are still, unknown to us.

The surface soil on which these plots are located consists of sand-ridge land typical of the upper terraces of the Murray River frontage areas. It consists of a very loose, sandy loam, in which the proportion of sand is very high. The sand therein ranges from a finely granulated, dusty, grey-colored powder to a very coarse, gritty, reddish soil body. The former type occurs most freely in small patches, chiefly in the plots to which phosphatic fertilisers were given, and the coarse, red-colored type predominates throughout the nitrogen and potash treated sections.

During the progress of the trials, 45 holes were sunk midway between every alternate row of trees in the plot devoted to phosphatic fertilisers and 35 at similar intervals throughout the nitrogen and potash dressed areas.

This was done to ascertain, as correctly as possible, the nature and depth of the soil above the limestone marl and to note, at the same time, the penetration of the root systems of the trees, and, incidentally, that of the irrigation water.

The surface of the phosphatic-dressed area presents a gentle slope to the south-west by south, whilst that receiving the nitrogen and potash turns towards the south-east, facing the morning sun. A study of the borings indicates that the greater depths of soil in these plots are found along the lower margins of their slopes.

In the phosphatic tests the soil depths ranged from 7in. to 33in. above the sandy marl, the average depth over the whole plot being 18.5in., the top row holes indicating an average depth of 13.2in. and the lowest row 18.5in. above the sandy marl. The soil depth is greater in the nitrogen and potash plots, ranging from 10in. in one small but higher spot, to 45in. at the lowest southern corner before the sandy marl is reached.

The average along the channel outlets on the upper margin of these plots is 13.5in. and along the lower end of the water run 38.3in. The average depths of loam over these two plots is 25.7in. above the sandy marl. The sandy marl in most soundings persists for nearly a foot deeper before the actual marly clay of varying consistency is reached.

Observations made relative to root penetration indicated that scarcely any roots were found below the sandy loam and practically none had penetrated into the marly clay which, in most parts, underlaid the sandy marl. It may be assumed, therefore, that the principal root activities take place in this soil in the layer extending from below the plough depth, say, 7in., to 30in. below the surface of the land, or approximately in a stratum 2ft. thick. In the area occupied by phosphatic tests the clay marl apparently defines the rapid penetration of the irrigation water before it begins on this sloping ground to move down the face of the substrata to find an outlet at some lower level. In the area devoted to trials with nitrogen and potash the marl probably contains less clay and rapid percolation takes place through it.

The procedure adopted in applying the fertilisers consisted of ploughing a furrow from 7in. to 8in. deep along each side of the row of trees and skirting the spread of the boughs in the direction of the water run. Owing to the steepness of the slopes, the water in most instances could not be directed diagonally across the spaces between, or, in other words, to evenly soak the soil all around the trees.

The quantity of fertiliser used per tree was distributed by hand along the bottom of this furrow and another furrow slice of soil turned over it. The irrigation water was then run down this second furrow until it had thoroughly soaked through the bank which covered the fertiliser. The quantity of fertiliser applied each year was divided into two equal parts, one-half being applied in early spring, several weeks prior to the blossoming of the trees, and the other at mid-summer.

There are 15 tests in all, consisting of four with water soluble phosphoric acid (superphosphate) applied at the rates of 3, 6, 10, and 12cwts. per acre, two with water insoluble phosphoric acid (bonedust) at the rates of 605lbs. and 1,008lbs. per acre, and two each with readily available nitrogen (sulphate of ammonia) and potash (sulphate), each at the rates of 2cwts. and 5cwts. per acre respectively. Of the two tests dressed with a "complete fertiliser," one receives a combination consisting of superphosphate—6cwts. sulphate of ammonia—2cwts. and sulphate of potash—2cwts. per acre rate respectively; whilst the other receives 605lbs. of bonedust, 2cwts. sulphate of ammonia, and 2cwts. of sulphate of potash per acre rate respectively.

Sandwiched in amongst these test rows are three rows which were not manured during the first eight years, but retained as checks upon the results obtained from the fertilised rows. Each of the barrier rows which separate the rows under test from each other receives on its side a quantity of fertiliser approximately equal to half the quantity of the particular fertiliser or fertilisers which is being applied to the test row immediately adjacent to that side. It follows, therefore, that barrier rows receive unequal dressings on either side of the trees, the aggregate quantity being different from that given the test row which stands adjacent on either hand.

The records of produce and the general development of the trees in these barrier rows afford in many instances a means of direct comparison with the effects resulting from the application of quantities of the various fertilisers intermediate between those weights applied to the accredited trial rows.

Each test in the plot dressed with water soluble phosphoric acid now contains 10 trees. The complete fertiliser containing superphosphate was given to nine trees, and that containing bonedust in lieu of superphosphate to eight trees only. Each barrier and no manure check row in this plot carries 10 trees.

In the water insoluble phosphoric acid dressed plot, the test row which received 605lbs. of bonedust contains six trees, as also does the row to which 1,008lbs. of bonedust is given. The no-fertiliser check row here holds four trees only. These reduced numbers arose from the abandonment of portion of the land after the first five years' operation owing

to the development of a "salt patch" at one corner of that particular area. Prior to this development the rows fertilised with superphosphate carried 17 trees, and those receiving bonedust and complete fertilisers ranged from 16 to seven trees each. The trees in the plots receiving superphosphate, bonedust, and "complete" fertilisers are planted 24ft. apart on the square system = 75 trees per acre. Those in the nitrogen and potash trial plots are set out on the rectangular system, 22ft. x 20ft. = 99 trees per acre.

A close scrutiny of the trees in each test row has revealed that what are popularly known as "off type" Navel trees were very prevalent. This term as applied to Navel orange trees refers generally to the coarse character of the fruits borne. They usually have rough, thick, and oftentimes corrugated skins, and in some instances a tendency to lack juiciness. These trees are almost invariably distinguishable by their upright gross limb growth and large leaves, whilst a tendency to display shyness in cropping is also not an uncommon characteristic attributable to them.

Although, unfortunately, the cropping data of the individual trees was not recorded in the first eight years of these trials, it will be observed from the accompanying tables that the shy cropping habit was not a consistently outstanding feature of the "off type" trees in those tests in which there was appreciable response to the fertiliser applied—as indicated by comparison with the unmanured check rows. For instance, in the plot treated with water soluble phosphates, the rows dressed at the rates of 3cwts., 6cwts., and 10cwts per acre showed 7/9ths, 7/10ths, and 3/5ths respectively of their trees to be "off type" Navels, whilst the row receiving the 12cwts. per acre had no "off type" forms. This preponderance of "good type" trees was the case also in the unmanured check row which stands next but one remove away.

After these trials had been conducted for eight years, viz., 1920-1928, the results, as indicated in the figures of fruit yields as set out in Table I., together with the comparative condition of health and growth observable in the trees, demonstrated beyond doubt that the immediate limiting factor in the growth and productiveness of citrus trees in such soils in the Murray Valley was the restricted supply of nitrogen in the land. In no instance where this element was omitted, or where inadequate quantities of it were applied, was there any consistent response in the form of improved tree condition or increased cropping capacity displayed. This lack of improvement was particularly emphasised in the plots to which either potash or soluble phosphates were applied. The hundred trees which the former plot held gradually ceased to grow and assumed a sickly, yellowish green color in the leaves. The fruits, with few exceptions, fell with the first outburst of summer heat. This feature is clearly emphasised in the season 1928 (see Table I.), when five rows consisting of 83 trees bore only 605lbs. of oranges, or approximately 12 bushel cases. It may be incidentally mentioned this fruit was generally small in size and possessed a very smooth, pale yellow skin over a sweet, solid pulp.

The trees in the tests receiving water soluble phosphates, though less anaemic in appearance, made poor growth, and, as Table I. indicates, cropped very sparingly. Their fruits, though deeper in color on the rind than those in the potash tests, were somewhat less sweet to the taste, and the skins were thicker, though not unduly coarse.

In the rows receiving mixed fertilisers and water insoluble phosphate (bonedust) the trees gradually improved in health and cropping capacity. The fruits from these trees displayed a deep orange-colored rind, distinctly thicker than that on those gathered from the potash and soluble phosphate treated trees. The pulp was juicy and quite well balanced in flavor. This very gradual increase in rich, healthy green foliage and in crop production leads us to suspect that the nitrogenous factor, viz., 3.25 per cent. contained in the bonedust, which was absent from the tests hitherto described, had much influence in creating these effects. The trees in the tests dressed with sulphate of ammonia began at an early stage in these trials to indicate that when used at rates of from 3cwts. per acre upwards improvement took place. The trees assumed a vigorous deep green appearance which was well maintained throughout the whole period, whilst the crops soon increased far beyond those in the plots fertilised with other forms

of plant foods. The fruits borne on these trees developed a deeper orange-red color on the rind, which was itself somewhat rougher and crisper than that found on fruits produced upon trees in any of the other plots. The pulp, however, proved to be juicy and not over sweet. The failure of the superphosphate dressed trees to yield profitable crops or make reasonably good growth, and the palpable decline in health and cropping capacity displayed by those to which potash alone was applied demanded a change of treatment in which nitrogen should be included. It was resolved, therefore, in 1929 that the plot constituting the trials with water soluble phosphates should be divided transversely into two sections, and, besides continuing to apply the superphosphates as heretofore to the various rows, one-half of the trees in each row should, in addition, be dressed with sulphate of ammonia at the rate of 5cwts. per acre, whilst the other half should receive stable manure at the rate of approximately 12 tons per acre—deemed to contain an equivalent in nitrogen to the above quantity of ammonium sulphate.

The plot, in which the trees were formerly fertilised with potash only, was also similarly subdivided into two equal parts. Each of the rows were to receive their dressings of sulphate of potash as heretofore, but at the same time one-half of each row was to be given sulphate of ammonia at the rate of 5cwts. per acre, whilst the other (the upper) half would be dressed with an equivalent in nitrogen from an organic source, viz., blood manure, at the rate of 7½cwts. per acre. Excepting the stable manure, which is ploughed in during the winter, these additions of nitrogenous dressings are divided into three parts—one being applied in early spring, another towards mid-summer, and the third later in summer—each put in with its respective irrigation. Between these subdivisions, in both the phosphatic and potash tests, a barrier row was set up at right angles to the run of the irrigation furrows.

This amended programme was put into operation in the spring of 1929, and the tests thus treated are each indicated by a cross in Table I. Table II. gives the resulting crops from the whole of the amended test rows for the year 1930.

As only one year's cropping results are available from the tests receiving the amended dressings, no comment is offered at present. Suffice it to say that to anyone who had previously viewed these plots, the changed condition of growth which has taken place in the trees in all of these amended trials needs to be seen to be properly appreciated. From the sickly, aenemic condition previously described they have, after undergoing only two seasons of the changed treatment, become transformed into healthy, vigorous trees, carrying this season (1931) an exceptionally heavy crop of fruit of splendid appearance.

The accompanying tables bring the results of these trials up to year 1930. In a paper contributed by the Manager of the Orchard to the *Journal of Agriculture of South Australia*, July 15th, 1929, pages 1010-1012, the results of the first eight years' operations and the yields from the actual test rows are set out in graphic form. An analysis of the costs and returns quoted in that paper showed that owing to the extraordinary yield gathered during the first year from the potash trial, dressed at the rate of 2cwts. per acre, that test was able to show an average profit of 8s. 5d. on the eight years' work in spite of gradually diminishing returns throughout the subsequent seven years. The position of this particular test, as shown by its yields, compared with those of the other potash dressed trials, will be the object of further inquiry in the future.

The outstanding feature of the analysis of the cropping data over the eight years' period referred to was the equivalent of an average annual profit of £22 3s. 6d. per acre indicated as the result of applying sulphate of ammonia to a plot of trees at the rate of 5cwts. per acre. In Table I. herein it will be noted that over a 10-year period the yields of oranges from an adjoining barrier row which has received each year a dressing equal to 4½cwts. of sulphate of ammonia per acre have, during eight of those years, exceeded those in the test row above referred to, averaging up to about 12½ cases per acre per annum over the 10-year period. This result will be further examined in subsequent work.

TABLE I.

| Block. | Row. | Fertiliser Applied, Rate per Acre.                                                                                                                       | Yearly Yields in Lbs. per Acre. |           |          |          |           |           |
|--------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|-----------|----------|----------|-----------|-----------|
|        |      |                                                                                                                                                          | 1921.                           | 1922.     | 1923.    | 1924.    | 1925.     | 1926.     |

As in Table I., the underlined are test rows.

## COW JUDGING COMPETITION.

During the adjournment for luncheon at the Pruning Competitions held at Mypolonga on June 4th, a Cow Judging Competition was conducted at Mr. S. Cheetham's dairy, under the auspices of the local Branch of the Agricultural Bureau. Nineteen competitors entered. Mr. L. Haynes won the adult section and Master H. Rowley was awarded first place in the Junior Section.

Mr. P. H. Suter (Senior Dairy Instructor), who acted as judge, expressed pleasure at the action of the Branch in organising the Competition—the first of its kind which had been held. Such tests of skill, he said, would do much towards inducing the young people to take a live interest in animal husbandry, and it was a lead which could be well followed by other Branches of the Bureau in dairying centres.

So successful was the Competition that it was decided to make this an annual fixture, and to stimulate further interest Mr. Suter has donated £2 2s. as a first prize for next year's Competition, and Messrs. T. Dodd and J. O'Brien offered 10s. 6d. each for a second prize.

## SOURSOP TROUBLES.

[By A. R. HICKINBOTHAM, B.Sc. (Chemist) and W. G. BENNETT, B.V.Sc. (Veterinary Officer), Roseworthy Agricultural College.]

### INTRODUCTION.

The soursob (*Oxalis cernua*), which originally came from South Africa, and was introduced here as a garden plant, has established itself so well locally that it now forms the most prominent part of many pastures during the winter months. One often hears it referred to as a useful pasture plant that provides an abundance of herbage in the early winter months; at the same time it is regarded with suspicion because of its content of oxalic acid, a substance poisonous to stock.

From chemical considerations, and from observation, it was thought that soursob had an influence on the occurrence of twin pregnancy disease in sheep and milk fever in cattle; that is, that soursob grazing could be a predisposing factor in both diseases. To test this theory with regard to sheep, a good deal of investigation has been conducted at the College this year, and in several cases sheep have been treated on neighboring farms. It will probably not be possible to complete the investigation of certain phases of the work this year, but enough has been done to assert with confidence—

- (1) That twin pregnancy disease (toxæmia of pregnancy) is accentuated by grazing ewes in lamb upon soursob and a large proportion of losses could be prevented by avoiding soursob grazing;
- (2) that early treatment in such cases as do occur with ewes approaching lambing will give good results;
- (3) that soursob poisoning in general is successfully treated by the administration of suitable calcium compounds.

### SOURSOP AS A FODDER PLANT.

An analysis of soursob plants, taken when about three-quarters grown, gave the results set out in Table I., in which, for comparison, the analyses of young barley, lucerne, and mixed pasture are also given.

TABLE I.—Composition of Green Fodders.

| Percentages—          | Water. | Crude Protein. | Crude Fat. | Crude Carbohydrate. | Crude Fibre. | Ash. | Oxalic Acid. | Starch Equivalent. |
|-----------------------|--------|----------------|------------|---------------------|--------------|------|--------------|--------------------|
| Soursobs . . . . .    | 92     | .83            | .28        | 3.55                | .98          | .71  | 1.65         | 4.0*               |
| Green barley . . . .  | 81     | 2.5            | .5         | 8.8                 | 5.6          | 1.6  | —            | 9.6                |
| Green lucerne . . . . | 76     | 4.5            | .8         | 9.3                 | 7.8          | 2.2  | —            | 9.1                |
| Mixed pasture . . . . | 80     | 3.5            | .8         | 9.7                 | 4.0          | 2.0  | —            | 11.1               |

(\*Assuming complete digestibility.)

The sap of all plants is acid, but the amount present is generally small, and, further, the acids usually occurring are not nearly so "strong" or "active" as oxalic acid is. The oxalic acid in soursobs appears to be present to a large extent as free acid, whereas in other plants the acids occur mostly as salts and acid salts, and are, therefore, less active.

In three-quarter-grown soursobs the total oxalate content was 1.65 per cent. of the green plants. Of this, nearly one-half (.70 per cent. of green plant) was present as free acid, the remainder being insoluble in water, and probably occurring in the plant as calcium oxalate. In the presence of excess hydrochloric acid (as in the later stages of

spectacular, and recovery often occurs within a few minutes. The explanation is that, in building the skeleton of a foetus, there is a steady drain on the calcium of the blood. This drain is greatly increased as soon as the milk supply begins (milk is rich in lime), and the animal goes down with milk fever. By adding calcium to the blood normal conditions are quickly re-established and a cure effected. The older treatment of pumping up the udder produces the same results indirectly and much less rapidly.

The etiology of twin pregnancy disease does not appear to be so simple. It is stated that any lack of calcium in the blood will restrict the function of the liver in removing poisonous waste products, and any condition of the animal likely to bring about a lowered calcium content in the blood will necessarily give rise to symptoms of poisoning (toxaemia).

Among stock-breeders the term "twin pregnancy disease" is used to include two diseases, known for example in New Zealand as "Ante-partum paralysis" and "Lambing sickness." Both occur locally, the former being characterised by fatty degeneration of the liver and other organs, is more commonly met with, and is correctly named Toxaemia of Pregnancy. The latter condition, on which data is scarce, appears to be akin to milk fever.

Symptoms of milk fever in cattle develop when the calcium content of the blood falls below a critical point, and this sometimes occurs before calving. In sheep this trouble seldom occurs after the lamb is dropped, but high producing ewes, especially of the larger breeds and with twin lambs, do frequently suffer from milk fever after lambing, and, as stated, this trouble is sometimes included under the term "twin pregnancy disease."

There seems no reason to suppose that sheep do not suffer from ante-partum milk fever; in fact, considering that sheep produce relatively little milk compared with cows, it might be expected that ante-partum milk fever in ewes would be more common than post-partum trouble. However, so far as experience goes, we have met no case of ante-partum milk fever in sheep not complicated by toxaemia of pregnancy. The question arises whether these two diseases exist—generally more or less associated with each other—or whether toxaemia of pregnancy is actually ante-partum milk fever in the ewe. Nothing in our experience negatives this suggestion, and there is a good deal of evidence to indicate that they are closely allied.

However this may be, a similarity between "twin pregnancy disease" and milk fever emerges when the conditions leading up to these diseases are considered. Milk fever is discussed above. "T.P.D." often occurs when the ewe is carrying only one lamb, but it is more frequent, as the name implies, when two are carried. In this case the drain on the blood calcium is much greater for two foetuses than for one, and ewes with two lambs are most likely to succumb.

#### OXALIC ACID REDUCES BLOOD CALCIUM.

If, after an animal has been poisoned with oxalic acid from soursobs, the organs are examined for oxalic acid, it will be found—

- (1) That in the stomach *free* oxalic acid occurs;
- (2) in all other organs—liver, kidneys, bladder, &c.—the oxalic acid occurs in combination with calcium as crystals of *insoluble calcium oxalate*.

Thus the oxalic acid which passes through the stomach walls and enters the blood combines with the *calcium of the blood* precipitating it as insoluble calcium oxalate, and completely removing it as far as its normal functions are concerned.

The absorption of oxalic acid, therefore, reduces the amount of calcium in the blood. Consequently, if animals predisposed to "twin pregnancy disease," with a somewhat lowered calcium content in the blood, are grazed on soursobs, the oxalic acid contained in them further lowers the calcium content—probably below the critical point when the animal goes down. In many cases the animal would escape a critical sickness if the oxalic acid were avoided.

## ILLUSTRATIONS.

1. In one instance a flock of sheep, due to lamb in a few days, were changed from sown green feed to a pasture of barley-grass and soursob. Next morning eight ewes were dead and about 20 more were showing symptoms of poisoning. *Post-mortems* on some of the sheep showed twin lambs in two and fatty degeneration and the characteristic T.P.D. smell in all. Drenching the remainder with calcium cleared up the trouble, including a ewe that had been unconscious for 24 hours, without further loss.

2. In another case eight deaths were reported and treatment asked for. This farm was visited. Some sheep showed unmistakable T.P.D. symptoms; others were apparently typical soursob cases. All cases were ewes close to lambing; dry ewes, wethers, and ewes with lamb at foot were unaffected. One ewe, very low and showing typical T.P.D. symptoms, was treated subcutaneously and later drenched. She was walking within 24 hours, but died the following night. *Post-mortem* showed peeling of the stomach lining (oxalic acid). Another showing typical acid poisoning symptoms and paralysis of the front legs recovered within two hours of drenching.

These two instances, selected from several similar cases, illustrate that soursob accentuates T.P.D.

3. Some 15 ewes due to lamb at different times within a month, and five wethers, were placed in a yard and fed heavily on chaff with the object of causing T.P.D. if possible, without any soursob complication. This treatment produced cases within one week, while all the wethers remained healthy. About half the cases showed typical T.P.D. symptoms, but the rest were not typical, and the material was therefore not very satisfactory to work on.

In all, seven cases occurred; four were typical and were treated with calcium as a drench or subcutaneously. Of these, one was lost, two recovered, and the other, after improving considerably; died after two days; *post-mortem* showed that the foetus had been dead for at least a day. Both dead ewes showed typical T.P.D. anatomical changes. All of the others were lost, and *post-mortems* disclosed causes of death other than T.P.D., though fatty degeneration had commenced.

These cases show the calcium treatment effective (in part at least) in T.P.D. cases not complicated by oxalic acid poisoning. Probably results would have been better under more natural conditions.

4. In several cases dry ewes and wethers have been placed on soursobs with the object of producing poisoning. About 10 cases occurred and all recovered on drenching.

It might be added that soursob poisoning occurs about 10 times in ewes for every once in wethers—this is a common observation. The ewes, because they are breeding, tend to have a low calcium tension of the blood and are, therefore, more susceptible.

## TREATMENT.

*Soursob Poisoning.*—The drench that has given good results consisted of—

Calcium chloride—5 grams=level teaspoon.

Ammonium chloride—5 grams=level teaspoon.

Water— $\frac{1}{2}$  pint.

The calcium chloride renders any oxalic acid in the stomach insoluble so that it can do no further harm, and the remainder passes easily through the stomach wall and corrects the calcium content of the blood. The ammonium chloride is used to reduce bloating and for its tonic effects.

*Twin Pregnancy Disease.*—If taken sufficiently early the same drench has proved successful. (In bad cases hypodermic injection made subcutaneously has given a rapid response, the animal being considerably brighter in 10-15 minutes, but the animals developed serious sores where the injections were made. It is intended to try future cases intravenously, as in the milk fever treatment.)

## CONTROL.

*Precautionary measures against soursob poisoning* (this applies to all sheep, but particularly to ewes in lamb).

1. Lime in drinking water (if taken) will prove of benefit.
2. On the first sign of trouble drenching the flock will save losses. This treatment cannot be regarded as at all permanent, as all the calcium will be eliminated in probably two days.
3. Hungry sheep must not be placed on soursobs. Feeding with oats damped with calcium chloride (about 1oz. to six sheep) and molasses before placing on soursob has been effective.
4. A change to grazing on lucerne or clovers (which are rich in lime).
5. Sheep from areas where soursobs do not occur should be got used to them gradually.
6. If possible sheep should be removed to other pasture than soursobs at least once every two weeks.

Regarding point 1, the addition of lime to drinking troughs has, in a local herd, greatly reduced the incidence of milk fever. This apparently has supplied sufficient calcium, and will lessen liability to the trouble, especially where the cows graze on soursobs.

Regarding points 3 and 4, fifty sheep were taken for experiment with these treatments, and divided as follows:—

- A. 20 were fed on oats damped with calcium chloride solution.
- B. 20 were grazed till satisfied on lucerne.
- C. 10 were fed on chaff.

Within 24 hours of placing the flock on soursobs one case of poisoning occurred, and 24 hours later another case developed—both were sheep from group C. No sheep of A or B showed any symptoms within 10 days.

*Control of T.P.D.*—It is now well known that exercise and sparse rations up to the time of lambing greatly reduces losses from this cause. Our work on this point is not sufficiently advanced to state definite conclusions (and further material is not available this year), but it appears that the addition of a calcium complex to the ration will at least reduce the possibility of trouble. If such cases as occur are treated by drenching as above when symptoms first appear, it is considered that a proportion of cures will result. Past experience has been that only about 2 per cent. of T.P.D. cases recovered, but this year two out of four similar cases recovered when treated.

## IRRIGATION INVESTIGATIONS IN THE MILDURA AND RENMARK DISTRICTS.

[A Paper read by Mr. A. V. LYON, M.Agr. Sc. (Commonwealth Research Station, Merbein), at the Conference of River Murray Branches of the Agricultural Bureau, Renmark, June 18th, 1931.]

### GENERAL.

The general method of control of the distribution of irrigation water in a Murray River settlement provides that an Advisory Board, on which the settlers have the major representations, decides the periods of the year at which irrigation water is made available to the settler, and that the method by which the water is to be applied, and the durations of the irrigations, is essentially in the hands of the settler.

### THE PRESENT POSITION.

The results of the irrigation practices in many of our irrigation settlements are by no means satisfactory. Associated with the periodicity or frequency of watering, we have had errors arising from a protracted period between irrigations; and, on the other hand, the methods of irrigation have been such, that salt and seepage problems have become acute, and are still increasing, in lands liable to these troubles.

Temporary water shortages, unless extreme, fortunately leave no permanent effects on the health of the vine, which usually recovers in one or two seasons, during which decreased yields and low-quality products are in evidence. With citrus trees, temporary shortages of water have more prolonged effect, and may entail reconditioning of the trees by cutting out dead wood.

Salt and seepage problems are much more serious, and have permanently decreased productivity, and in extreme cases, rendered the land wholly unproductive. In less acute cases, crop losses may be periodic, vines and trees temporarily going out of condition when spells of very hot weather are experienced or irrigation has been unduly delayed.

It will thus be seen that the problem is twofold, having to do with both the method and the frequency of irrigation.

The investigations in progress have been designed to secure information on each of these two problems.

Data is being secured in the Renmark, Curlwaa, and Mildura districts, on a number of selected sites, representing the major soil types. The investigation has taken the form of measurements of soil moisture, in the periods between irrigations; and of the immediate changes in soil moisture, as a result of irrigations. The latter includes the location of the spread of water from an irrigation furrow, represented by a soil moisture profile in a vertical section of the soil across the furrow.

Results show that the soil moisture changes over September, October, and November period (12 weeks) are comparable to the changes occurring in each of the two subsequent five-week periods between irrigations. This is particularly interesting, in that present practice includes, on the major portion of our horticultural lands, irrigation within this 12-week period. A relatively low moisture content at harvest is also disclosed.

The total changes in soil moisture from August 8th to December 2nd, 1929, on a deep loam soil were also measured. On this occasion the growth curve of the vine shoots was recorded. The results observed on the vine and the soil-moisture measurements indicate that suitable soil-moisture conditions were maintained throughout the

period, without the application of irrigation water, and confirms the results obtained the previous year. It is of interest to note, also, that the major soil-moisture changes occur within 18in. of the surface.

Soil moisture changes at two Renmark sites were taken during the 1930-31 season. Again we have indications of limitation of the depth of soil-moisture changes. A high moisture content throughout the season, during which the usual irrigations were supplemented by regular rainfall, is a feature of the irrigation practice during this season.

Irrigation on Renmark soils has a marked influence on the water table. In the case of type 3 soil, the rise of the free water levels closely follows the irrigation. In the type 6 soil there is considerable delay, probably due to the heavy clay subsoil above the free water surface.

Soil-moisture profiles, resulting from furrow irrigation in different soil types, vary with the soil type. These show that the soil profile, particularly increases in the clay content with depth, profoundly affect the results from irrigation, tending to increase lateral and decrease the natural vertical penetrations.

#### SOIL MOISTURE PROFILES.

The study of soil-moisture profiles from one furrow discloses that the shape of the profile changes as irrigation is prolonged, the lateral distribution showing a relative increase. An outstanding result on the data secured is the advisability of three or more furrows for irrigating, to secure adequate and economical wetting of the soil. In the common case of one-furrow irrigation per vine row of 10ft. spacing, the surface soil is wetted only when irrigation is prolonged until the downward penetration is retarded or stopped by a layer of clay, and the lateral penetration has proceeded until it meets the profile of the adjoining furrow. This necessitates accumulation of free water. A similar result, of lesser extent, prevails with two-furrow irrigation, as the natural turnip-shaped profile is not sufficient in lateral measurement to meet the requirements until penetration is hastened by retardation or stoppage of the downward flow. With three-furrow irrigations, for vines spaced at approximately 10ft., the top-shaped profile, resulting from an increased clay content with depth, is sufficiently wide to wet the top soil without accumulations of free water.

The measurements of lateral penetration suggest the suitability, for many of our soils, of furrows spaced at approximately 3ft.

This spacing is now being applied to horticultural lands with plants of wide row spacing, such as citrus and stone fruits. In the Mildura district, the term "multiple furrow system" is arising, and is displacing the former practice of irrigating in furrows widely spaced.

#### SOAKAGE RATE.

The time necessary for complete wetting of the top soil, from irrigation furrows at 3ft. spacings, may be stated at 12 hours or less for the majority of soil types, the heavy clays being possible exceptions. A reduction to half this time is possible on some soils. On small sections of the furrow, into which the introduction of the water may be almost simultaneous and the soakage rate measured, the initial absorption of water is fairly rapid, with a very decided decrease in the soakage rate as irrigation proceeds.

Measurements have been taken in reference to the clay loam (blue bush) soils in the Mildura district, on which it had previously been ascertained that the soakage rate was reduced to approximately one-third of the initial amount after an interval of three hours. Irrigation water was delivered into the furrow at the rate of 1gall. in 13 secs. and at this rate the water reached the end of a 6-chain run in 6 hours. The delivery was then reduced to one-third (1gall. in 40 secs.), with the result that the water at the end of the furrow receded slightly (1yd. in one hour), and within the next three hours receded 21yds. and recovered to the full length of the furrow. In the succeeding 12 hours, the water, without alteration of the delivery rate, remained in the full furrow

length without overflowing. The behavior of the water in two adjoining furrows, at 3 ft. spacings, showed no marked difference. In this instance, the measured rate of application is  $4\frac{1}{2}$  ac. in., a very considerable reduction on general practice.

Examination showed complete wetting of the whole of the upper 3 ft. of soil, excepting in places at the surface at the midline between the furrows. On this line, dry soil up to 10 in. wide and a few inches deep was in evidence intermittently. This result, and its subsequent application to a larger field, illustrates quite clearly the practicability of marked reductions in the duration of irrigation, and consequently in the amount of water used.

An additional advantage is a reduction of over-soakage, manifest under present practice on the higher portions of the irrigated tract. In this connection, it is essential to have suitable devices for control of the water flowing out of the irrigation ditch, and also to determine by trial the necessary alteration of the soakage rate, as irrigation proceeds, for the principal soil types.

#### FREE WATER.

It may be generally stated that present practices, considered in relation to the subsoils of the irrigated land, result in water logging of portions of each irrigation settlement. In certain soils, such as the Type 3 of the Renmark area, excessive watering appears to have no harmful effect, apart from unnecessary expense in pumping and the probable wastage of portion of the plant foods.

In the case of other heavy soils, such as Type 6, Renmark, excessive waterings result in the formation of surface pools, in the removal of which evaporation probably contributes. As shallow rooting of horticultural plants is a characteristic of such soils, there appears no necessity for deep penetration of irrigation water. In soil moisture determinations on an extreme Type 6 soil at Renmark, three-furrow irrigation for 24 hours wetted the soil to its full field capacity, and no decided increase in soil moisture resulted from 48 hours flooding. The reservation must be made that these results may not hold in a dry, hot season, in which loss of water to greater depths in the subsoil is possible. So the problem again resolves itself into one of unnecessary expense, with the added probability of interference with the plant by the total submergence of roots, which, in the Renmark district, has been observed to prevail for periods up to seven days after irrigation.

On lands which are potentially salty, exemplified in portions of the Mildura, Berri, and Barmera districts, it is certain that excessive waterings are making the main contributions to the salt devastation, which is increasing each year. The present practice, by which free water surface is raised at each irrigation and amelioration sought by agricultural drains, is not always satisfactory.

The following conditions of agricultural drainage in the Mildura district have come under notice:—

- (i.) Drains laid in a permeable subsoil layer at depths of approximately 4 ft. with free water held by an impermeable or semi-impermeable layer at a greater depth. Such drains function only when the water level is raised to the level of the drains.
- (ii.) Drains laid in a soil layer sufficiently impermeable to form a temporary or perched watertable, which is usually accompanied by a more impermeable layer, and a more permanent watertable at a greater depth. Drains under these conditions function for a limited time following irrigation, removing only the upper surface of free water.
- (iii.) Drains laid on the impermeable layer in soils which are limited to one such layer. The effective removal of free water is possible under these circumstances.

In the absence of a complete survey, no attempt is made to define the relative occurrence of these three common cases. The examples are cited to illustrate the importance of a study of the soil profile and of the occurrence of free water in relation to irrigation.

# Scientific Farming!

**THAT** is the only proper response to present troubles—**THAT** is the road to solvency and restored prosperity. . .

Economies are necessary, but to cut the application of super in this years farming effort would be a fatal mistake. .

Science and Economy dictate the liberal use of

## W.M.L. EXTRA HIGH-GRADE SUPER

for it lowers costs by increasing yields.

in all agricultural drainage considerations. Of the cases cited, only one, Case (iii), effectively provides against salting.

For removal by downward leaching of salt, provision must be made for removal of excess free water; or, alternatively, limitation of the irrigation supplies to the extent that free water occurs for brief periods, if at all. It is in these directions that relief from the menacing salt troubles might be found, as limitation of the duration of irrigation tends to limit free water movement to a downward direction.

#### COMMUNITY IRRIGATION PRACTICE.

The results of irrigation investigations and observations are being utilised in community irrigation practice.

The general practice, illustrated by the record of irrigation at Merbein over a period of years provides for water service at the following periods:—

1. A winter irrigation, completed before the end of August.
2. An early spring irrigation, completed before the end of October.
3. A late spring irrigation, completed on approximately December 20th.
4. A mid-summer irrigation, commencing in late December and continuing until early irrigators have received an additional (pre-harvest) irrigation.
5. An autumn special (late February or March) for citrus and late grapes.
6. A late autumn (usually in April, on completion of harvest) for growth of cover crops.

Occurrence of rain necessitates slight alterations, and heavy rains may warrant omission of an irrigation. A common example is the omission of the winter irrigation in seasons of heavy winter rainfall.

It has been shown that the soil moisture changes during spring are insufficient to warrant an early spring irrigation. Persistence in this irrigation must be attributed to a fundamental fault of community irrigation, in that up to four weeks is necessary for the service of the whole settlement. As a result, late irrigators take water in October, not because it is needed at the time, but to enable their plants to carry over until they are again served near the termination of the irrigation commencing in late November. On the other hand, early irrigators can and do forego the October watering, as they are first served at the succeeding period. The utilization of this fact by growers in increasing numbers is a recent change in irrigation practice in the Mildura district, and has resulted in a marked decrease in the total water used at the early spring irrigation.

In reference to the requirements in the Autumn period, the present arrangements are entirely unsatisfactory, as a special charge at the Mid-harvest irrigation contributes to faulty practice. Growers frequently withhold irrigation on land that is in need of it, until the Late Autumn irrigation, when water is again available under the annual charge. Excepting for revenue purposes, there are no advantages in this, as in the majority of cases, the Mid-Autumn irrigation would suffice for the season in lieu of the present late autumn service, which is usually not received until wilting of leaves has occurred.

#### CONCLUSION.

It is appropriate to point out, in conclusion, that any steps which tend to shorten the individual period for irrigation tend also to shorten the community period. Under present conditions, in many of the settlements, the decision to irrigate must be made five weeks in advance of the anticipated service to the final irrigators. With a shorter community period, a delay in the decision is practicable, useful rains in the intervening period frequently resulting in decided savings in both settlers' labor and irrigation service. As the efficient minimum service is thus accompanied also by preservation of capital value of the irrigated lands, decreased distribution costs, and the possibility of utilising natural rainfall to a greater extent, decreased application of irrigation water may be stated as a first essential in overcoming existing soil difficulties and in reducing costs.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

## CONFERENCE OF RIVER MURRAY BRANCHES.

Branches of the Agricultural Bureau situated in the irrigated districts of the River Murray met in Conference at Renmark on June 18th. There were present Professor A. J. Perkins (Director of Agriculture), Messrs. G. Quinn (Chief Horticultural Instructor), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Poultry Expert), N. S. Fotheringham (Manager Berri Orchard), B. L. Griffiths, E. Leishman, J. B. Harris, F. R. Arndt, H. Beriman (District Instructors), H. C. Pritchard (General Secretary), F. C. Richards (Assistant Secretary Agricultural Bureau), Professor J. A. Prescott (Waite Agricultural Research Institute), and A. V. Lyon (Merbein Research Station), and delegates from the Berri, Renmark, Waikerie, Block E, Ramco, and Light's Pass Branches.

## OPENING CEREMONY.

In welcoming Departmental officers and delegates from visiting Branches, Mr. O. Weste (Chairman) said:—We as primary producers fulfil a very important part in the rehabilitation of our country's financial stability in so far as the goods we produce for export comprise about 80 per cent. of our production, and in this way create new wealth to the country's coffers. We gather together once a year in conference to listen to the deliberations of those who have made a deep study of their subjects, and it would be hard to get a better combination of interesting subject matter than we have with us to-day on the agenda, nor can we have better men to deal with their subjects. The Agricultural Bureau system is of vital importance to the growers all over the State, whether it is wheat, wool, dried fruits, and some of the most far-reaching and important matters dealing with the agricultural and horticultural industries have been brought about by the influence of this institution. There is no reason why membership should not be 100 per cent. of primary producers, instead of which we have a comparatively small band of willing workers, who feel it a deep duty not only to keep in touch with all matters of interest, both practical and scientific, but who willingly distribute this information throughout the land. I would specially like to welcome the Director of Agriculture, who so kindly consented to open this Conference, and those who have so willingly prepared papers, and hope their efforts will be appreciated by those present. I would also like to say a word of deep regret for the illness of our very dear friend, Mr. H. S. Taylor, and I am sure we all wish him a speedy recovery.

## THE DIRECTOR'S OPENING ADDRESS.

In his opening address, Professor Perkins (Director of Agriculture) said:—In the first place I must express regret at the circumstances that have thrown upon me the responsibility of delivering the Opening Address at this Conference. The original intention was, as your agenda shows, that it would be delivered by your local representative on the Advisory Board of Agriculture, Mr. H. S. Taylor. We all regret his unfortunate absence to-day, and I know that I shall be rightly interpreting your feelings in expressing our deep sympathy with him in his illness, and our hope that he may soon be on the way to recovery.

## TRIBUTE TO MR. H. S. TAYLOR.

I think I can say without any exaggeration that in the length and breadth of the Murray Valley there is no man who has labored more unselfishly and more successfully for the progress and development of the River settlements than Harry Taylor. I have had the privilege of his acquaintance for a number of years, and I do not hesitate to state that in the course of a tolerably long life I have not met a whiter man; nor do I

think that I shall do so in the few years that remain to me. His instinctive reaction has always been towards the weaker side; he has shown himself the sworn champion of those least able to defend themselves, and the last defender of many a lost cause. If I had to describe him as briefly as possible I should say that essentially he was an idealist, whose idealism was tempered by a considerable fund of shrewd common sense; and it is this happy combination that has made of him so valuable a public man to the district which he has elected to serve. It might be added, too, that although without guile, he combines the innocence of the dove and the wisdom of the serpent. And during the course of this Conference we shall miss not only the pithiness of his Opening Address, but in addition the illuminating comments which he has usually contributed to our debates. That he should be able to resume his normal activities at the earliest possible moment is the heartfelt wish of us all. Let me, too, apologise for the absence of the Minister, whose official duties unavoidably detain him elsewhere.

#### A COMPREHENSIVE AGENDA.

My experience of these Conferences extends back to a number of years; indeed, back to the earliest days of the Agricultural Bureau system, and I have observed that the most successful Conferences are usually held when times are hard in the country. In spite of recent improvements, they are none too bright at the present time, and logically we should anticipate a most successful Conference to-day. In this connection, I feel that I can congratulate you on the comprehensiveness of your agenda. In addition to the normal items, I notice that you are to have an address on "Water Penetration" by Mr. A. V. Lyon, who has, I understand, conducted research work on the subject at Merbein; and another address on "Soil Problems" by Professor Prescott, who is a world authority on the subject. I take it that both addresses will deal with matters of immediate importance to all of you.

#### THE DRIED AND CITRUS FRUITS POSITION.

Your main interests lie so much in the direction of dried fruit, that after a succession of depressing seasons, it must be highly gratifying to you all to find that your leaders and those best able to form an opinion on the matter are beginning to take an optimistic view of the dried fruit position. This means, of course, that overseas market prices are likely to be more favorable than those of recent years. It would seem that you owe this partly to the misfortunes of others in the shape of untimely frosts and generally unfavorable seasons; but partly, too, to improvement in quality and uniformity of your marketable produce. On the latter count you are to be congratulated on the local organization and co-operative spirit that have led to these results. Nor in this connection should the values of judicious propaganda and the search for new markets be overlooked. Under the influence of the new trade treaty our prospects on the Canadian market would appear to be very bright. I understand that the Export Control Board estimates that the 1931 exportable surplus of Australian dried fruits is not likely to exceed 30,000 tons, of which 10,000 tons will probably be absorbed by Canada and New Zealand. The latter should relieve the pressure on the London market and lead to a general improvement in mean prices.

Many of you, too, are interested in citrus fruit; and it must be highly gratifying to you to realise the dominating position which River fruit, and particularly South Australian River fruit, occupies on the markets of the Commonwealth. It is true that we are rapidly approaching a large Commonwealth surplus in citrus fruit, and that our overseas marketing problems in this direction have not yet been completely solved. The study of them, however, is in competent hands, and in the course of time we are entitled to anticipate the development of a successful export trade which will contribute materially to the wealth of the State.

I need not dwell upon the importance of high quality and uniformity of sample in produce intended for the markets of the world; a policy of slackness in this direction is likely to undermine the best efforts of those who are endeavoring to build up a successful export trade.

## SIDE LINES.

There is one other point on which I should like to say a few words. Except for the fact that in days of general unemployment they find themselves in continuous employment, there are very few primary producers to-day whose financial position is altogether comfortable, and in consequence there has been a more or less general tendency to look around and see whether sidelines might not help, when main lines are precariously situated. This is certainly the case of wheat farmers, who in increasing numbers are turning their attention to cows, sheep, pigs, and poultry, without, however, relaxing their efforts to grow wheat; and it is not only legitimate, but essential, that they should do so. But you, no doubt, consider yourselves specialists to an even greater extent than the average wheat-grower, and imagine that sidelines can help you but little. Personally, however, I cannot imagine that your orchards and vineyards should be entirely self-sufficing—there must be material, by-products that usually go to waste; there must be odd corners that could be exploited to some advantage. What these sidelines should be I am not prepared to discuss in detail, beyond stating that the association of live stock of any kind with crop growing has numerous indirect advantages apart from any profits it may bring. I notice that Mr. Anderson is to address you on poultry, and I hope he will convince you that poultry can do more than supply your breakfast requirements, although in these times the latter are not to be despised. Mr. Barlow, too, will be in attendance to give full information on the advantages of cows and pigs.

I have very much pleasure in declaring the Conference open, and I trust that your deliberations will be of advantage both to yourselves and the River districts as a whole.

## PRESENTATION TO MR. H. S. TAYLOR.

The high esteem in which Mr. H. S. Taylor is held by the Bureau was exemplified by a presentation of a fine clock and fountain pen, in the making of which the Chairman spoke as follows:—

In making this presentation on behalf of the River Branches of the Agricultural Bureau, I would like to say that no man on the River is held in higher esteem than is Mr. Taylor. We hold him in esteem not only as an authority on matters of horticulture and on matters of the history of organised marketing, but whatever matters he has taken into his heart he has delved right to the core of the matter and given us the deliberations of that vast brain of his. We hold him in very deep affection as a staunch friend—a friend who can be relied upon in any emergency, and as a journalist he is at his best when fighting for a just cause with his back to the wall.

We have seen him fighting for our industry, the very existence of which depended upon legislation being passed that did not find approval with one of our strong daily papers.

**WE ARE BUYERS AT HIGHEST MARKET PRICES**

TELEPHONE C. 4255-4256.

He has crossed swords with many who have regretted it. But best of all, we like our peaceful idealist who has made his home a reflection of himself—in his garden to wander amid fruits and flowers, to retire to his library and listen for a while to that fund of literary wealth stored from the world's best works and retained by a master mind.

We wish Mr. Taylor to accept these gifts not because of their value, but because we feel a very deep gratitude to him, and we wish him to accept our appreciation in some small way of the work he has done for our Agricultural Bureau. Mr. Taylor has always been more than indulgent to his critics, and allowed them a degree of latitude not tolerated by any other paper, showing as it does the magnanimity of his nature. As a friend and councillor his long association with the Advisory Board stands to his everlasting credit, and we hope he will long continue to carry on the good work. The clock will remind him that time exists for rest as well as work; and the longer he rests, the longer will he enjoy the use of his fountain pen.

---

### REPORT ON SULTANA PRUNING TRIALS, JUDGED ON, CROP RETURNS.

---

[Held under the auspices of the Berri Branch of the Agricultural Bureau at the vineyard of Mr. P. M. Wilksch, of Berri, during the seasons 1928-1929, 1929-1930, and 1930-1931.]

---

[By N. S. FOTHERINGHAM, W. R. LEWIS, and F. R. ARNDT.]

The idea that in Pruning Competitions the crop produced, as well as the actual pruning of the Vines, should be taken into consideration, has for some time been the opinion of a number of Sultana growers, who hold to the belief that the pruning of this vine, both in general practice and at Pruning Competitions, has been based too much on theoretical standards, without sufficient regard being paid as to how the methods used by pruners affect crop returns.

The statement has also, at times, been made that neatness and symmetry often appear to be the chief objective of many pruners at Pruning Competitions, and that the vines are not always pruned in a manner to enable them to produce the highest crops in accordance with their strength.

The expression of such views during the past few years has led to some extent to greater uncertainty among Sultana growers as to pruning methods, and has made it desirable that these ideas should be tested, so that the effect that pruning methods have on crop returns should be more clearly understood.

#### THE WILKSCH CUP.

The present pruning trials owe their inception to the initiative of Mr. P. M. Wilksch, of Berri, who offered portion of his vineyard for the purpose of holding a Pruning Competition under the auspices of the Berri Branch of the Agricultural Bureau, in which the pruners would be judged according to the total weight of fresh fruit produced during the three consecutive seasons of 1928-1929, 1929-1930, and 1930-1931, but that the shape and general wellbeing of the vines at the end of that period should also be taken into consideration by the judges in giving their award.

As an incentive for growers to enter these pruning trials, Mr. Wilksch presented a silver cup for the winner of the Competition. The Berri Branch agreed to take charge of the Competition, and appointed Messrs. N. S. Fotheringham, W. R. Lewis, and F. R. Arndt to act as judges. To further encourage pruners to enter as competitors, the Berri Branch offered to give the sum of £2 2s. as a second prize.

## THE SITE OF THE EXPERIMENT.

The land chosen for the site of the experiment consisted of good, fertile, deep, sandy red loam. The vines were in good heart—strong and vigorous—and had been well pruned and cared for. During the first year that the experiment was in progress the vines were manured with 3 cwts. of blood and bone manure per acre, but during the two following years the only fertilisation that the land received was that given by the ploughing in of cover crops of peas and beans; but these, on account of the dry weather conditions, produced only a moderate amount of growth. Each competitor was given a row of 46 vines to prune, and he pruned the same row every year.

The nature of the soil and the general condition of the vines was practically the same for each row. The vines all received the same treatment in regard to fertilization, irrigation, and tillage operations, and the shoots were all tipped during the growing period on the "Voullaire" system—all of which work was performed by Mr. Wiksch.

## THE COMPETITORS.

The competitors who took part in the pruning trials were Messrs. B. H. Jungfer, G. H. Botttrill, E. R. Moss, A. G. Jarvis, J. R. Johnson, W. N. Ellis, A. W. Magarey, and L. A. Chapple. The vineyard numbers of the rows selected for the pruning trials ranged from 11 to 18, and in this report, with one or two exceptions, the competitors are referred to by the number of the vine rows they pruned.

## OBSERVATIONS ON PRUNING METHODS.

The judges attended the pruning trials each year, and observed the methods used by the various pruners. The chief points upon which information was obtained include:—

1. The number of fruiting canes left by each pruner per vine per year.
2. The number of spurs left by each pruner per vine per year.
3. The system of pruning adopted by the various competitors.
4. The approximate average number of fruiting buds left by each competitor per vine at the 1930 pruning trial.

In regard to the pruning methods used by the competitors, these resolved themselves into two main systems. Of these, the method of depressing the fruiting canes on to wires lower than the crown of the vine was adopted by Competitor No. 14, but the previous training of the vines did not make them suitable for this kind of pruning. The system adopted by the remainder of the competitors was that of choosing suitable fruiting canes and of twisting them on to the trellis wires, the chief difference between the competitors being in the number and length of the canes selected.

## METHODS USED BY PRUNERS.

Briefly stated, the main features of the pruning methods adopted by the various competitors were as follows:—

*Competitor No. 11.*—This pruner relied on numerous strong fruiting canes, averaging 7.3 canes per vine, and left more fruiting rods on the vines than any other competitor.

*Competitor No. 12.*—Made use of numerous fruiting canes of moderate length, which were on an average, shorter than those left by any of the other competitors, and averaged six canes per vine.

*Competitor No. 13.*—The fruiting canes selected by this competitor were long and strong and were tightly wound around the trellis wires after pruning. The number of fruiting canes used by this pruner was less than those of any other competitor, and averaged five per vine.

*Competitor No. 14.*—As previously stated, this competitor worked on the system of depressing the fruiting canes of the vines. As, however, the vines had previously been trained with crowns close to the bottom wire of the trellis, they did not lend themselves well to this class of pruning. The fruiting canes selected averaged 7.2 per vine.

*Competitor No. 15.*—Made use of a moderate number of well selected fruiting canes, ranging from three to seven per vine, and averaging 5.6 per vine.

**Competitor No. 16.**—This competitor chose numerous strong and fairly long fruiting canes, and averaged 6.1 canes per vine for his fruiting wood.

**Competitor No. 17.**—Selected a moderate number of fruiting canes, and averaged about 5.6 canes per vine.

**Competitor No. 18.**—This competitor relied on a fairly large number of well-selected rods for his fruiting wood. The number of canes left varied from about four to eight, according to the strength of the vines, and averaged 6.1 per vine.

#### WEIGHING THE FRUIT.

The fruit was weighed by Mr. Wilksch, who took every precaution to ensure that the weights were correctly taken.

The following is the record of the weight of fresh fruit produced during the course of the experiments:—

#### *Weight of Fresh Fruit in Lbs.*

| No. of Competitor. | 1929. | 1930. | 1931. | Total. |
|--------------------|-------|-------|-------|--------|
| 11 .....           | 2,178 | 1,957 | 803   | 4,938  |
| 14 .....           | 2,133 | 1,949 | 856   | 4,938  |
| 16 .....           | 2,215 | 1,804 | 782   | 4,801  |
| 18 .....           | 2,083 | 1,799 | 723   | 4,605  |
| 15 .....           | 1,995 | 1,756 | 685   | 4,436  |
| 13 .....           | 1,839 | 1,773 | 772   | 4,384  |
| 12 .....           | 1,683 | 1,823 | 643   | 4,149  |
| 17 .....           | 1,703 | 1,532 | 668   | 3,903  |

From the above figures it will be observed that the Competition resulted in a tie, as the two leading competitors—No. 11 (Mr. B. H. Jungfer) and No. 14 (Mr. A. G. Jarvis)—both secured the same weight of fresh fruit. The weight of fruit obtained by the majority of the competitors was high for the first two years, but fell off considerably during the 1931 season, which was a year of general low sultana yield throughout the Murray Valley. The aggregate weight of fresh fruit secured during the three years by the lowest competitor was 21 per cent. below that obtained by the highest.

#### EQUIVALENT ANNUAL AVERAGE WEIGHT OF DRIED FRUIT PER ACRE.

Worked out on an acreage basis from the foregoing figures, the average annual crop of dried fruit for each competitor for the three years, if calculated at the ratio of 3½lbs. of fresh fruit to 1lb. of dried, would represent the following weight in pounds:—

| No. 11. | No. 14. | No. 16. | No. 18. | No. 15. | No. 13. | No. 12. | No. 17. |
|---------|---------|---------|---------|---------|---------|---------|---------|
| 4,831   | 4,831   | 4,697   | 4,505   | 4,339   | 4,289   | 4,059   | 3,868   |

The relation of the number of fruiting canes left on the vines to the total weight of fresh fruit obtained by each competitor gives the following results. The number of spurs is also given, but no conclusions have been drawn therefrom:—

#### RELATION OF NUMBER OF FRUITING CANES TO CROP RETURNS.

| No. of Competitor. | Total Number of Fruiting Canes for Three Years. | Total Number of Spurs, Three Years. | Total Weight of Fresh Fruit, Three Years. | Order of Competitor in Relation to Crop Return. | Order of Competitor in Relation to Number of Fruiting Canes. |
|--------------------|-------------------------------------------------|-------------------------------------|-------------------------------------------|-------------------------------------------------|--------------------------------------------------------------|
| 11                 | 1,007                                           | 496                                 | Lbs.<br>4,938                             | 1 } &                                           | 1                                                            |
| 14                 | 991                                             | 455                                 | 4,938                                     | 1 } 2                                           | 2                                                            |
| 16                 | 845                                             | 457                                 | 4,801                                     | 3                                               | 3                                                            |
| 18                 | 844                                             | 346                                 | 4,605                                     | 4                                               | 4                                                            |
| 15                 | 785                                             | 558                                 | 4,436                                     | 5                                               | 6                                                            |
| 13                 | 695                                             | 262                                 | 4,384                                     | 6                                               | 8                                                            |
| 12                 | 830                                             | 492                                 | 4,149                                     | 7                                               | 5                                                            |
| 17                 | 774                                             | 287                                 | 3,903                                     | 8                                               | 7                                                            |

The preceding table shows that the first four competitors secured crop returns in the same order as the number of fruiting canes left on the vines, but this did not apply to the competitors lower down on the list. It must, however, be realised that this method of finding the relationship between the number of fruiting canes and vine yields can be approximate only, as the fruiting rods, being of various lengths, cannot all be of the same value for fruiting purposes.

#### BUDS PER VINE.

It was, therefore, considered that the number of buds left on the fruiting canes would probably give a more accurate ratio to crop returns than that given by the number of fruiting rods only. Accordingly, after the pruning operations for the 1930 season had been completed, it was decided to count the number of fruiting buds left on the vines by the pruners. However, as it was realised that the counting of the buds on all of the vines would occupy more time than the judges were able to give to this work, the buds on six typically pruned vines only of each competitor were counted and averaged per vine, and the number so obtained was in each case used as the average number of buds per vine for each competitor.

The relation of the number of fruiting buds to the weight of fresh fruit is shown in the following table:—

1931 Crop—Relation of Number of Buds to Fruit Yields.

| No. of Competitor. | Appr. Average Buds per Vine. | Total Weight of Fresh Fruit, per 46 Vines, in Lbs. | Average Weight of Fresh Fruit per Bud in Lbs. | Order of Competitor in Relation to Fruit Yields. | Order of Competitor in Relation to Number of Buds. |
|--------------------|------------------------------|----------------------------------------------------|-----------------------------------------------|--------------------------------------------------|----------------------------------------------------|
| 14                 | 90                           | 856                                                | ·2067                                         | 1                                                | 1                                                  |
| 11                 | 81                           | 803                                                | ·2155                                         | 2                                                | 2                                                  |
| 16                 | 66                           | 782                                                | ·2576                                         | 3                                                | 3                                                  |
| 13                 | 64                           | 772                                                | ·2622                                         | 4                                                | 4                                                  |
| 18                 | 63                           | 723                                                | ·2494                                         | 5                                                | 5                                                  |
| 15                 | 58                           | 685                                                | ·2567                                         | 6                                                | 6                                                  |
| 17                 | 53                           | 668                                                | ·2739                                         | 7                                                | 8                                                  |
| 12                 | 54                           | 643                                                | ·2588                                         | 8                                                | 7                                                  |

The above figures show that in the case of the six highest competitors, these secured fruit yields in the same order as the number of fruiting buds left on the vines. However, the column relating to the average weight of fresh fruit produced per bud shows that the buds were not all of the same value for fruiting purposes, and this will explain why the two last competitors do not follow in the same order on the list as the others, as this is shown to be due to No. 17 selecting fruiting buds of slightly superior quality to those of No. 12. It will be observed that Competitor No. 14, who used the largest number of fruiting buds per vine, namely, 90, obtained the lowest weight of fresh fruit per bud. The results of the experiments for the three years seem to show that, generally speaking, the competitors who gave their vines the most to do obtained the best returns, which in a great measure is probably due to the nature of the vines, which on account of their vigor were able to respond to such treatment, whereas weaker vines may not have done so.

#### PRESENT CONDITION OF THE VINES.

On present indications the condition of the vines pruned by all of the competitors appears to be favorable for the production of a good crop for the coming season. On some of the vines pruned by the three leading competitors, however, there has been a tendency in some places for the fruiting wood to run rather far away from the crown of the vines, making it necessary in such cases for these vines to be shortened back more severely in the future.

## RECOMMENDATIONS OF JUDGES.

As the Competition has resulted in a tie, the judges would recommend, with the consent of Mr. Wilksch, that the pruning trials be extended for another three years, but that the prize of £2 2s. offered by the Berri Branch of the Agricultural Bureau should be equally divided between the two leading competitors, namely, Messrs. B. H. Jungfer and A. G. Jarvis. The judges would also point out as an encouragement to the other competitors that their vines, probably owing to having been pruned more severely, are at present in a somewhat better condition in regard to the position of their fruiting wood than those of the pruners who so far have obtained the largest crops. This should result in their securing good crops in the future, whereas the leading pruners, through having more severely taxed the strength of their vines in the past, may find it necessary, in trying to stimulate their vines to more vigorous growth, to prune these in a more drastic manner during the coming years, which may result for a time in a decline in their yield.

---

**THE MARKETING OF CITRUS FRUITS.**

[By F. H. METTERS, Waikerie.]

In a paper submitted to a previous Bureau Conference I dealt with the care necessary by the producer and packer of citrus fruits to ensure the fruit reaching its destination in as near perfect condition as possible, and I now propose to treat with the actual disposal of the fruit on the market, and the means adopted by the several State Citrus Associations and the Federal Citrus Council of Australia in the regulation of the supply of oranges to the market and the stabilisation of prices.

History records that in the past the marketing of practically all primary products has been undertaken in a most haphazard and uncontrolled manner, and this applies to most sections of agricultural products at the present time, with the result that there are periods of heavy over-supplies on the markets at consequent unprofitable returns to producers. In 1921 citrus growers were faced with many serious problems on the markets in Adelaide and Melbourne, which brought into existence the present co-operative organisations.

The two principal factors governing the successful marketing of any product of the land are:—1, the control by the producers of their particular produce; and 2, the regulation of supplies to the market concerned. Because of the bearing these two features have on efficient marketing, I cannot too strongly stress the need for the close and loyal co-operation of the grower, failing which only chaos can result.

In framing the policy of the Citrus Associations, one of the first essentials was to ascertain the possible requirements of the market at a selling price profitable to the owner of the fruit. As a result, the quota system was introduced, whereby the amount of fruit forwarded is adjusted from time to time in accordance with market requirements, great care being taken to neither overload or under-supply a market.

A team of suitable agents, having a large turnover, and who were prepared to work in with our ideas of marketing, was selected, and it has been proved without doubt that with a limited number of agents more control could be obtained at the marketing end than by giving our business to the whole of the agents operating on the market, provided growers confined the selling of their fruit to the selected agents.

Subsequently the Federal Citrus Council of Australia, which operates for the joint State interests, appointed its own market manager in Melbourne, whose duties are to fix quotas, stabilise prices, inspect fruit, issue reports, inspect agents' books, authorise repacking and cool storage, pass account sales, and watch associated growers' interests generally. These interests are further fully protected in the matter of the rate of selling commission, guaranteed payments, and fire insurance.

The buyer on the market to-day is a very particular person, and carefully scrutinises every pack that comes before his notice, and it is only by close attention to the preparation of his pack that a grower can hope to realise top market value and ready sale.

Fruit that is not up to the buyer's idea of a standard is either passed by or sold at a discount. It should be seen to that all fruit is kept rigidly in its respective classification, Special, Standard, or Plain. For instance, one Plain orange noticed in a case of Standards will probably reduce the value of that case to that of the lower grade. The container should be packed sufficiently tight to ensure its arriving full. A partly filled case obviously will not realise full-case value; but the costs of packing and transport are identical. Although South Australian oranges have held pride of position on the Melbourne market for many years, other centres are fast overtaking us, and every attention should be given to the establishment of a first-class pack.

It is considered advisable to either print an indelible trade name on the rind of the fruit, or use an attractively printed wrapper, confining this to Specials or Standards; but this practice should be adopted only on fruit that will induce the consumer to repeat his order.

All fruit should be free of scale or sooty mould, otherwise it is likely to be condemned by Departmental inspectors. Dry or frosted fruits should under no circumstances be marketed; it is ruinous to the trade generally. An Act of Parliament operates in Victoria dealing with the maturity of oranges, and, although the means of testing for maturity are by no means perfect, the Act gives the inspectors power to prohibit the offering of fruit for sale that does not comply with the regulations.

In Victoria and New South Wales oranges must be placed into Special, Standard, or Plain grade, which are defined in the Act, and the case marked accordingly. This regulation is strictly enforced by the departments concerned.

To summarise, the following are the principal factors governing the buyers' attention:—

1. Continuity of supply.
2. Standardisation of grading for color and weight.
3. Evenness of sizing.
4. Degree of maturity.
5. Tightness of pack and a full case.
6. Elimination of off-type fruit and culls.
7. Correct classification under the headings, Special, Standard, or Plain.
8. An attractive case neatly stencilled or labelled.

Although in the past Australia has consumed its own production of Citrus Fruits, at prices remunerative to the producer, the time has arrived when we are faced with the necessity for export, and the Federal Citrus Council is inquiring into every possible avenue in this direction. The high costs of production in Australia and the depressed economic conditions the world over, and consequent low values, are no incentive for growers to send oranges overseas; but as the position has to be faced, fruit is this season being dispatched to England, Canada, and the East.

In the years 1921 to 1925 the Murray Citrus Growers' Co-operative Association, Limited, was quite successful in export, and the fruit was stated, by all who handled it overseas, to be at least equal to any other marketed at that time. Since 1925 no export has been undertaken by that body, but this season 6,000 export cases of navel oranges, each of 1½ bush., are being shipped to England in July, and, as a decided improvement has taken place in both the quality and the packing of the fruit, exporters should expect to realise top market value.

One of the many difficulties encountered in connection with export is the reluctance of most shipping companies to accept oranges as freight, when commodities such as tea, flour, butter, eggs, &c., are carried, the orange being liable to taint such cargo. Pre-cooling of the fruit, however, tends to reduce this risk.

Valuable assistance is being given to marketing, both local and export, by the several Departments of Horticulture and the Council for Scientific and Industrial Research. Recently the latter body issued recommendations for the harvesting and packing of oranges for export, being the results of its investigations.

In conclusion, I desire once again to impress upon those interested in citrus marketing, either local or export, to associate themselves wholeheartedly with the co-operative movement in order that the fruit will sell to the best advantage, and at a minimum marketing cost. Never before has joint effort and control of supplies been more needed than at present. The actions of even a small number of growers operating independently invariably tends to reduce market values. If all citrus growers were confining the sale of their fruit to the accredited agents of the Citrus Associations, prices would be several shillings per case higher than those now obtaining.

## SUMMARY OF REPORT ON SULTANA DRYING EXPERIMENTS DURING THE 1931 SEASON.

*[Conducted conjointly by the Council for Scientific and Industrial Research with the Horticultural Branch of the Department of Agriculture of South Australia on vineyards situated at Berri and Renmark.]*

[By F. R. ARNDT, Horticultural Instructor.]

These experiments in Sultana drying were undertaken with the object of collecting data in regard to various systems used in the drying of Sultana grapes, and to ascertain how the quality of the fruit, when dried, was affected by the nature of the soil upon which it was grown, and by the climatic conditions operating during the drying period. The experiments were conducted at the vineyards of Messrs. Basey and Howie, of Renmark, and of Mr. J. Partridge, of Berri.

The Council for Scientific and Industrial Research was represented at the experiments by Mr. A. C. Ingerson, of Berri, acting under instructions from Mr. A. V. Lyon, M.Sc., of Merbein, who collaborated with myself in carrying out the work.

The different dipping systems experimented with were as follows:—

The Cold Carbonate of Potash Dip.

The Standard Hot Mixed Dip.

The Ingerson Dip.

The Modified Hot Caustic Soda Dip.

Two series of experiments with the above-mentioned dips were conducted at each of the vineyards previously referred to.

### FIRST SERIES OF EXPERIMENTS.

The first series of experiments were conducted at Berri and Renmark between February 17th and March 9th, under good weather conditions, the highest maximum temperature being 101.6° Fahr., and the lowest maximum 69° Fahr. No rain fell during the drying period.

The fruit treated was of good quality at both vineyards, the Renmark fruit, which registered 12° Baume, being a little sweeter and of a more golden color than the Berri fruit, which showed a sugar test of 11½° Baume, and was greener in color.

The soil upon which the fruit was grown was in both cases a firm clay loam, of which the Renmark soil was slightly the firmer of the two.

### STRENGTH AND TEMPERATURE OF DIPPING SOLUTIONS.

The strength and temperatures of the dipping solutions used were as follows:—

*Cold Potash Dip.*—Strength, at rate of 25lbs. carbonate of potash and 1½ pints of olive oil to 50galls. of water. This formula was used at both vineyards.

*Standard Mixed Dip.*—At Berri—Strength, 2½lbs. carbonate of potash, 2lbs. caustic soda, and 1½ pints of olive oil to 50 galls. of water. Temperature, 178° to 181° Fahr. At Renmark—Same temperature and strength as at Berri, with the exception of a reduction of ½lb. of caustic soda.

**Ingerson Dip.**—At Berri—Strength, 2½lbs. carbonate of potash, 1½lbs. caustic soda, and 2oss. of olive oil to 50galls. of water. Temperature, 187° to 190° Fahr. At Renmark—Same temperature and strength as at Berri, with the exception of about 3oss. increase in caustic soda content.

**Modified Hot Caustic Soda Dip.**—Strength—1½lbs. caustic soda to 50galls. of water. Temperature, 190° to 193° Fahr. This formula was used at both places.

#### THE TIME OF DRYING.

**At Berri.**—The time of drying from dipping to the placing of the fruit into sweat-boxes was as follows:—*Modified Hot, Standard Mixed Dip, and Ingerson Dip*=16 days. *Cold Potash Dip*=21 days.

**At Renmark.**—Time on rack—*Mixed Dip, Ingerson Dip, and Modified Hot Dip*=13 days. *Cold Potash Dip*=16 days.

Time from spreading on to rack until placing into sweat-boxes—*Standard Mixed Dip, Ingerson Dip, and Modified Hot Dip*=16 days. *Cold Potash Dip*=20 days.

The fruit treated by the Cold Potash Dip was in both instances sprayed with the Standard Cold Potash Solution three times while on the rack, and was washed after its removal from the rack.

The fruit treated with the Modified Hot Caustic Soda Solution was sprayed (with the exception of that situated on half of the top tier) with the Standard Cold Potash solution within 48 hours after spreading on the rack. The effect of such spraying was a very slight brightening up of the color of the dried fruit, but did not shorten the drying period as compared with the fruit that had not been sprayed.

#### QUALITY OF DRIED FRUIT.

**At Berri.**—The quality of the dried fruit was excellent, and the color, from light golden to more amber shades, occurred in the following order:—1. Cold Potash Dip. 2. Standard Mixed Dip. 3. Ingerson Dip. 4. Modified Hot Caustic Dip.

**At Renmark.**—The dried fruit was of a darker shade than that obtained at Berri. This may be chiefly accounted for by the more amber colored nature of the fresh fruit, and by the fruit not being shaded as much as in the Berri experiments. An interesting fact to note in this connection is that the fruit treated by the Cold Potash and Standard Mixed Dip formulas, which contain the largest amount of olive oil, was not browned as much by the direct rays of the sun as that treated by the other solutions containing less oil, showing the protection against sunburn accorded to fruit that has been well coated with olive oil.

The shades of color produced in the dried fruit by the different dipping solutions was from golden to darker shades in the following order:—

1. Cold Potash Dip. 2. Standard Mixed Dip. 3. Ingerson Dip. 4. Modified Hot Caustic Dip, thus coinciding in each instance with those of the Berri trials.

#### SECOND SERIES OF EXPERIMENTS.

The second series of experiments were conducted under less favorable weather conditions than those of the first series. The fruit was dipped at Berri on March 4th and at Renmark on March 5th. The highest maximum temperature during the drying period was 98° Fahr. and the lowest maximum 62° Fahr. Rain fell on March 13th, 52 points; March 19th, 5 points; March 20th, 5 points; March 21st, 7 points; March 22nd, 5 points; and April 1st, 30 points.

#### QUALITY OF FRESH FRUIT.

**At Berri.**—The fruit was of good quality, being from slightly greenish-yellow to bright golden in color. The sugar content was 13° Baume. **At Renmark.**—The quality of the fresh fruit was only fair, much of it being over-ripe, and there was a large number of dark, burnt berries on the bunches. The sugar content of the fruit registered 14° Baume.

The nature of the soil upon which the fruit was grown was, at Berri, a firm red loam with a moderate amount of sand in its composition, and at Renmark this consisted of a stiff red loam.

#### STRENGTH AND TEMPERATURE OF DIPPING SOLUTIONS.

These were in some instances varied from those used at the first series of trials, owing chiefly to the altered condition of the fruit, and consisted mainly of additions of caustic soda, in order to crack the berries sufficiently.

*The Cold Potash Dip.*—This was used at the Standard Potash strength of 25lbs. to 50galls. of water, but the olive oil content was raised from 1½ pints of olive oil to 2½ pints of that used at the first series of trials.

*The Standard Mixed Dip.*—Strength—2½lbs. carbonate of potash, 2½lbs. caustic soda, and 1½ pints olive oil to 50galls. of water. This strength was used at both Berri and Renmark, and is an increase in caustic soda of ½lb. to 50galls. *Temperature*—Berri, 177° to 181° Fahr. Renmark, 178° to 181° Fahr.

*Ingerson Dip.*—Strength, 2½lbs. carbonate of potash, 2½lbs. caustic soda, and 2ozs. olive oil to 50galls. of water was used at both places. *Temperature*, Berri, 184° to 188° Fahr.; Renmark, 183° to 186° Fahr.

*Modified Hot Caustic Soda Dip.*—Strength—At Berri, 2lbs. caustic soda to 50galls. water. *Temperature*—188° to 193° Fahr. At Renmark, 2½lbs. caustic soda to 50galls. *Temperature*—188° to 193°.

#### TIME OF DRYING.

*At Berri.*—Time on rack—Standard Mixed Dip, Ingerson Dip, and Modified Hot Dip =17 days. Cold Potash Dip=20 days.

Time from spreading on to rack to placing into sweat-boxes.—Standard Mixed Dip, Ingerson Dip, and Modified Hot Caustic Dip=20 days. Cold Potash Dip=24 days.

*At Renmark.*—Time on rack—Standard Mixed Dip, Ingerson Dip, and Modified Hot Dip=21 days. Cold Potash Dip=24 days.

Time from spreading on to rack until placing into sweat-boxes.—Standard Mixed, Ingerson, and Modified Hot Dip=22 days. Cold Potash Dip=29 days.

#### QUALITY OF DRIED FRUIT.

*At Berri.*—The dried fruit was of first class quality for all kinds of dips used, and the color, from light golden to slightly darker shades, varied in the following order:—1. Cold Potash Dip. 2. Standard Mixed Dip. 3. Ingerson Dip. 4. Modified Hot Dip—thus coinciding with the order obtained at the First Berri and First Renmark Series.

*At Renmark.*—The quality of the dried fruit produced was inferior to that produced at the other three series of drying trials, the fruit treated by the Cold Potash Dip especially darkening in color during damp weather, although it was not wetted by rain falling upon it. The fruit treated by the Ingerson Dip appeared to be the least affected by the adverse weather conditions. The color of the fruit, from light to dark, according to the different dipping processes, varied in the following order:—1. Ingerson Dip. 2. Standard Mixed Dip. 3. Modified Hot Dip. 4. Cold Potash Dip—thereby differing greatly from that obtained at the previous trials.

#### SUMMARY OF RESULTS.

The chief results obtained at these experiments in Sultana drying—as far as the conditions operating during the past season seem to indicate—are briefly as follows:—

1. That the Cold Potash Dip produces the finest colored sample of dried fruit, provided that the fresh fruit used is of first class quality and that weather conditions are hot and dry. However, with inferior fruit and unfavorable weather conditions the results obtained from the use of this dip are disappointing. Also, the drying period of fruit processed by this dip is from four to seven days longer than that treated by the other dipping systems under similar weather conditions.

2. That the Standard Mixed Dip and the Ingerson Dip (also a mixed dip) have consistently produced a lighter colored sample of dried fruit than that resulting from the use of the Modified Hot Caustic Soda Dip, while the drying period of the fruit is the same in both cases.

3. That trials with a dipping process between that of the Standard Mixed Dip and Ingerson Dip would probably give interesting results, as it is probable that the use of  $1\frac{1}{2}$  pints of olive oil to 50galls. of solution is excessive in the former dip, while the use of 2ozs. of olive oil in the latter dip is often insufficient to protect the fruit from sunburn, unless it is well shaded while on the racks.

I would therefore suggest that for next season a dipping system be tried, containing the following ingredients:—

2½lbs. Carbonate of Potash.

1½lbs. to 2lbs. Caustic Soda.

$\frac{1}{2}$  pint of olive oil to 50galls. of water, at a temperature of 180° to 185° Fahr.

4. Regarding the suitability of the dips used to the fruit produced on different classes of soil, no definite conclusion can be drawn from one year's trials, and further experiments are necessary to obtain fuller data upon this subject.

Mr. A. V. Lyon M.Sc. (Merbein Research Station) read a paper, "Water Penetration."

An address, "Management and Care of Poultry" was delivered by Mr. C. F. Anderson (Poultry Expert).

Conference decided that the 1932 gathering should be held at Waikerie.

At the evening session, Professor J. A. Prescott (Waite Agricultural Research Institute) delivered an address, "The Soils and Soil Problems of the River Murray Irrigation Areas."

## TREATMENT AND CONTROL OF WORM INFESTATION OF SHEEP.

[Extracts from an article on "The Control of Stomach Worms of Sheep" by Dr. Clunies Ross, *Journal of the Council of Scientific and Industrial Research*, May, 1929, with remarks [in brackets] by Officers of the Stock and Brands Department].

Control of worm infestation may be brought about by:—

- (1) Attacking the worms in the sheep by medicinal treatment.
- (2) Attacking the worms on the pastures by such measures as burning off and the systematic use of paddocks in such a way as to reduce the chances of sheep obtaining heavy infections.

### MEDICINAL TREATMENT.

In administering medicinal treatment to sheep, the object is not only to cure them of worm infestation, but, more important still, the object is to kill all the worms in them, so that they can no longer produce eggs to further contaminate the pastures. .

In practice, however, it is not possible to kill every worm, as there is no medicament known which can be guaranteed to do so, and also, in many instances, it is impossible to administer the medicament sufficiently often, but it is still possible to reduce losses from worms to a minimum and to convert what is unsound country into a payable proposition for sheep.

There are a number of drugs employed for the treatment of worms in sheep, the best of which at the present time is carbon tetrachloride. Less effective is copper sulphate (bluestone).

#### 1. *Treatment with Carbon Tetrachloride.*

**Dose.**—Lambs, 1 cubic centimetre or 17 drops; adult sheep, 2 cubic centimetres or 34 drops.

Owing to the small size of the dose, it may be conveniently administered either in gelatine capsules containing 1 C.C. or 2 C.C., or mixed with four parts of medicinal liquid paraffin, in which case the dose would be 5 C.C. (cubic centimeters) for lambs and 10 C.C. for adult sheep.

[One gallon of the mixture is sufficient to dose approximately 800 lambs or 400 adult sheep, and at a cost of 18s. per gallon the cost is approximately ½d. per lamb and ½d. per adult sheep per dose.

The advantages of this treatment over copper sulphate are:—

- (1) Smaller dose administered by a syringe.
- (2) Quicker to administer.
- (3) After administering, sheep can be allowed out to graze immediately.
- (4) Is effective also against liver fluke.]

**Before Treatment.**—The sheep are yarded overnight and dosed the following morning before being allowed food or water.

**Administration.**—If capsules are employed, they are best given by means of a small balling gun, which can be made by taking a piece of stiff rubber tubing about 9in. long and with an internal diameter of ½in. A plunger of cane or wood should be fitted so that it runs easily and smoothly in the barrel and sufficiently long to form a handle.

In order to avoid the danger of injury to the sheep's throat, a guard should be placed on the handle so that when the plunger is driven home, the end is not less than ½in. from the end of tubing, and the plunger should be rounded and smooth so that it will not break the capsule which is placed in the end of the tube.

The operator stands in front of the head, the catcher opens the mouth by grasping both upper and lower jaws, and the barrel is inserted and pushed back over the base of tongue, but not hard against the back of throat.

The plunger is then driven home smartly, but not too vigorously, and the gun immediately withdrawn as the jaws are released simultaneously. Capsules are administered in this way easily, but by other methods, such as using forceps, it is often uncertain and tedious.

When the liquid is used, it should be given by an all-metal syringe with a long, curved nozzle, holding exactly 5 or 10 C.C., according to dose required.

Syringes can be purchased which hold 10 C.C. with a thumbscrew on the handle of piston which can be regulated to control the dose if only 5 C.C. is required.

The syringe is filled with the liquid, the nozzle inserted over the sheep's tongue, and the syringe steadily emptied.

[*Precaution.*—Owing to carbon tetrachloride evaporating rapidly, the mixture should be well agitated at frequent intervals in the original container and only a small quantity poured into the vessel from which the syringe is filled.]

Of the two methods the liquid mixture is recommended as being cheaper and more convenient and easier to administer, but is sometimes not so effective as the capsules, owing to insufficient care being paid to keeping the mixture well shaken and losing carbon tetrachloride by evaporation, so that in some cases sheep may receive practically nothing but liquid paraffin.

On the other hand, the capsules, while much more expensive and less convenient to administer, contain a dose which is accurately measured, and no loss by evaporation can take place, so that every sheep receives the correct dose.

## PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1931—

### Eggs for Hatching and Day old Chickens

#### WHITE LEGHORNS.

EGGS.—10/- per setting of 15 Eggs. Incubator lots £2 per 100.

DAY OLD CHICKENS.—15/- per dozen. £5 per 100.

#### BLACK MINORCAS.

EGGS.—12/6 per setting of 15 Eggs. Incubator lots £2 10s. per 100.

DAY OLD CHICKENS.—17/6 per dozen, £6 per 100.

Free on Rail, Salisbury. DELIVERY, July, August, and September.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Victoria Square, Adelaide.

G. F. ANDERSON, Poultry Expert.

Precautions to be observed when dosing with carbon tetrachloride:—

- (1) In certain rare instances, carbon tetrachloride, though absolutely safe for normal sheep, in doses five to 10 times the size of that recommended may cause some mortality.

The cause of this mortality has never been satisfactorily explained in all cases, but one factor known to influence the toxicity of the drug is the presence of mineral deficiency in the pasture, lack of calcium being of paramount importance.

When sheep are running on calcium-deficient country they should be given a lick rich in calcium, that is a lick containing superphosphate, calcium phosphate, or bonemeal for one week prior to dosing.

- (2) Another precaution is to try the effect of the drench (when being used for the first time or after a long period has elapsed since the last treatment) on a small percentage of the sheep of different classes (i.e., lambs, ewes, wethers). If no ill effects follow this trial drenching, it should be perfectly safe to proceed with general drenching.
- (3) During the actual administration of the drug, the sheep should be held in standing position and the head not forced too far back or upwards, especially when the liquid is used, and the tongue and the lower jaw should be left free.

[In the case of capsules, do not hold the jaws shut after administration in case the sheep did not swallow it, because if the capsule should be retained in the mouth and be broken, it may cause the animal to suffocate owing to evaporation of the carbon tetrachloride and absorption by lungs.]

- (4) It is very necessary to obtain the drug from reliable firms, as an impure preparation may be both dangerous and ineffective.

[In South Australia reports have been received by the Stock and Brands Department of some untoward results following the administration of carbon tetrachloride.

In one case, by mistake, sheep were given 5 C.C. of the drug as a drench without any oil, and before the mistake was found out two or three died.

In another case, a number of lambs were given 10 C.C. of the mixture and developed swellings around the head for a couple of days, but otherwise no ill effects noted.]

## 2. Treatment with Copper Sulphate Solution.

Bluestone (copper sulphate) is administered in the form of a 2 per cent. solution of the drug in water, and is prepared as follows:—

Dissolve 8ozs. of bluestone in 3galls. of water, and of this give the following doses:—

|                                  | Fluid ozs. |
|----------------------------------|------------|
| Adult sheep . . . . .            | 2          |
| Two toothed . . . . .            | 1½         |
| Lambs, 6-12 months old . . . . . | 1          |
| Lambs, 3-6 months old . . . . .  | ½          |

In preparing the solution, use only hard, blue crystals of the drug, discarding all lumps that are white and powdery. Break up the lumps and dissolve in a little boiling water; then add cold water to make up 3galls. of solution in an enamel bucket.

Iron utensils should not be used owing to the corrosive action of the solution.

[Administer, using the same precautions as recommended for the carbon tetrachloride liquid. Three gallons of a 2 per cent. solution will be sufficient to drench approximately 230 adult sheep. (Three gallons is equivalent to 480 fluid ounces).

Until recently a 1 per cent. solution was recommended by the Stock and Brands Department.]

## TOBACCO CULTURE.

[By B. C. SCOTT, Supervisor of Experimental Work, and S. B. OPIE, Field Officer.]

(Continued from page 1165, *Journal of Agriculture*, June 15th, 1931.)

### BULKING.

After removal from the barn the leaf is bulked down, that is to say, is stacked, during which time it should pass through a mild ferment and improve in quality. It is necessary that it should be in the proper condition as regards moisture, otherwise trouble will be experienced. If the leaf is too dry it will be easily damaged, whilst if too wet, mould will quickly appear. Therefore, the leaf must be sufficiently pliable that it will open after being squeezed in the hand, and at the same time not so moist that the midrib cannot be easily snapped at about two-thirds of the way up the blade.

Bulks are made by placing the tobacco in stacks each two rows of leaves wide with the blades overlapping a few inches in the centre, and the butts outwards. The heaps should be as high as possible, and as long as convenient, as large stacks make for better leaf than smaller ones.

The tobacco may be bulked when still on the sticks, or, on the other hand, the leaves may be taken off. If sufficient sticks are available, the former method allows for easy and rapid handling. As the leaf readily absorbs moisture, the bulk should be kept some inches above the floor, thus allowing for free circulation of air. The usual procedure is to build on logs or low benches. On completion the stack should be covered with hessian, old bags, or rugs, &c., and lightly weighted down. The heap must be carefully examined every few days to see that it does not become over-heated. This may be ascertained by inserting the hand well into the leaves and noting the temperature, but a better plan is to place a thermometer in the centre of the stack, and if the reading should exceed 80° F. it will be necessary to pull down the bulk and rebuild. When rebuilding, the leaf which was originally placed in the centre of the bulk should be stacked in the outer layers. However, if bulked in the right condition the tobacco will not require turning, and after passing through this mild sweat, may be left untouched for some months, during which time it will improve in quality. On the other hand, if put down with too much moisture it may be necessary to rebulk two or three times, whilst the burning of fires in the bulking room to dry the atmosphere may prove advisable. Should mildew occur, due to fatty stems, the leaf may have to be returned to the curing barn for further drying out.

### GRADING.

The whole of the leaf secured from a tobacco crop is not of uniform quality, and, in order to demand the best prices, it must be graded into classes according to color, texture, size, and soundness. In this connection emphasis must be placed on the necessity for careful grading if maximum values are to be expected, and any doubtful leaves must always be placed in the lower class.

The colors must be kept as uniform as possible, and for this work a well lighted room is essential.

Before grading can be commenced the atmospheric conditions must be such that the leaf has been rendered pliable, and will permit of handling without damage.

## KEY TO COLORED PLATES.

### A.—Appearance of the Leaf at the Commencement of the Operation of Fixing the Color.

In the curing process the leaf is held in a humid atmosphere, and the dry bulb thermometer registering not more than 100° F. until the yellowish shade is pronounced. This is the critical stage in curing, as should the next stage be commenced before sufficient color has been promoted, the green matter becomes fixed in the cured leaf, and its value greatly reduced. On the other hand, if the leaf is allowed to become too yellow it may not hold the desired color throughout the remaining stages, and becomes dark in shade before drying is complete (see page 1165).

### B.—Lemon Yellow Leaf.

This type of leaf commands the highest prices, provided that it is also of good body, silky texture, tough, elastic, oily, of large size, with no holes or spots.

### C.—Bright Mahogany Leaf.

This is a very good class of leaf, and is only slightly less valuable than the lemon yellow type, provided that it possesses good texture, &c. It is found in fairly high percentages in the produce from the best growers in this State,

### D.—Dark Mahogany Leaf.

Third class leaf as regards color, but commanding good prices when light bodied and of fine-grained texture. This type is produced from rather heavy leaf carrying a fair amount of moisture, such as would be the case when grown on loam soils or when harvested late in the season.

B

C

D

The various classes into which tobacco may be divided are as follows:—

*Colors.*

|                           |                                                            |
|---------------------------|------------------------------------------------------------|
| Lemon yellow . . . . .    | Bright to pale-yellow color.                               |
| Bright mahogany . . . . . | Darker than yellow, ranging between bright orange and red. |
| Dark mahogany . . . . .   | Ranging between orange and dark red.                       |
| Dark . . . . .            | Consists of all darker colored leaf.                       |

*Texture.*

|                          |                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------|
| First quality . . . . .  | Light bodied, thin, elastic, silky leaves.                                                 |
| Second quality . . . . . | Leaves from the bottom portion of the plant with light body, but not so silky and elastic. |
| Third quality . . . . .  | Leaves of medium to heavy body.                                                            |

*Size.*

|                 |                        |
|-----------------|------------------------|
| No. 1 . . . . . | Large, sound leaf.     |
| No. 2 . . . . . | Small or damaged leaf. |

Included in the dark leaf would be the coarse, dark tobacco, whilst very poor class and green leaf would be kept quite apart from other grades.

It is not suggested that all these classes should be made up, and the number will depend upon the quantity of leaf available. The smaller growers will probably ignore

A pressed bale kept under pressure by two iron bars until tobacco is properly set.

(From Rhodesia Agric. Journal).

the texture grades, and class according to color and size of leaves. In any case it is not advisable to make less than half a bale of any grade, and preferably regard one bale as a minimum for each class.

**HANDING.**

After grading the leaf is made up into bundles of about 15 to 20 leaves, called "hands." In "handing" the butts are all placed together and another leaf of similar quality bound neatly round them, making a tie of about 2ins. in width. To commence wrapping, the tip of the binding leaf is inserted between the stems and the tie completed by slipping the end through the "hand." This makes a neat and convenient bundle which rarely comes untied.

**BALING.**

For presentation to the buyer, and later for consignment to the factory, tobacco must be baled. This operation should be carried out as soon as convenient after grading, in order that no further changes in color should take place, but it is important to see that the leaf is not too moist at baling time, and is stored in a dry place.\* A press is

necessary, but is not difficult to make, and simply consists of a bottomless box with a movable side, and a lid which fits easily inside the top. In principle it is exactly the same as a wool press. The inside dimensions are about 3ft. long, 1½ft. wide, and 3ft. high, and will press a bale of the same length and breadth, but about 2ft. in height. A bale of this size will contain about 200lbs. of tobacco. A sheet of hessian is first placed on the floor under the press, and the hands of leaf neatly packed into the box with the butts towards the outside, and tips in the centre. The corners are bound by crossing the previous layer. The press is filled to the top of the box, when the lid is placed in position with a cap of hessian beneath, and sufficient pressure applied by screws, or levers, to make a fairly firm bale of about 2ft. in height. As heavy pressure tends to discolor the leaf, it must not be too tight. The sides are then removed, and the hessian which had been placed on the floor sewn to that inserted under the lid. The ends of the bale are covered, the pressure released, and the wooden lid removed. The next step is to mark with the grower's brand or initials, the grade of leaf, and the number of the bale.

Side View after being pressed. The method of placing layers in bale is illustrated.

(From Rhodesia Agric. Journal).

#### MARKETING.

Quality leaf is readily saleable, but inferior tobacco, such as heavy, dark, green, or immature leaf, is always liable to be rejected.

In this State it has been the practice for the buyer to visit the property of each grower and submit a price for the various grades presented. Should the producer be dissatisfied with the values offered, he has either to await the visit of the next buyer or forward samples to manufacturers, who have no representative visiting South Australia. In the past we have produced comparatively little tobacco, and only the buyer for the British-Australasian Tobacco Co. has visited growers. However, with the increased production it is probable that in future years the representatives of other firms will endeavor to purchase local leaf on the farm of the producer.

Upon acceptance of the purchase price, the leaf is railed to Melbourne before the final payment is made.

Whilst discussing the question of marketing, we desire to pay tribute to the British-Australasian Tobacco Co. for the assistance they have so willingly rendered to the tobacco-growing industry in this State.

## YIELDS AND PRICES.

The actual yield of tobacco is no criterion of the value of the crop, as heavy, coarse textured tobacco producing high yields per acre will have low poundage value, and, in fact, may prove unsaleable.

The type aimed at in this State is fine textured, mild smoking cigarette or tight plug tobacco, and a high yield for such type is about 8cwts. of cured leaf per acre. The average yield secured in South Australia at present is probably not more than 4cwts., increasing to 6cwts. or 7cwts. per acre in the case of the more experienced growers. With irrigation and added experience our average yield will probably be very considerably increased in future years, and maximum returns of up to half a ton per acre will no doubt be harvested. However, if the acre yield exceeds this figure, a fairly high percentage of heavy textured tobacco is sure to be included in the crop, and such quality will command a lesser value per pound.

The prices secured have not been particularly high, as compared with those obtained in other districts in the Commonwealth, due, no doubt, to the lack of humid climatic conditions in South Australia. They have ranged from 3s. 2d. per lb. to as low as 6d. per lb., whilst some leaf has been rejected. The average return is approximately 2s. per lb., whilst the better growers and curers have received up to as much as 2s. 4d. per lb. for the whole of their crop.

The returns from tobacco are, therefore, very high, but emphasis must be placed on the fact that experience plays a very important part in determining the amount of revenue received by the grower. New tobacco producers will probably have to buy their experience, and, therefore, would be well advised to limit the area planted in the first year or so, until they have gained a sound knowledge of the requirements of the crop for the production of quality leaf.

## PESTS AND DISEASES.

Quite a number of pests attack tobacco, and, if not kept under control, will frequently cause very considerable damage. On the other hand, whilst diseases are not so numerous, that known as blue mould has a most injurious effect upon the tobacco industry of Australia.

## PESTS.

Lucerne Flea (*Smynturus viridis*).—At times this pest causes much damage in the seedbed. It is very small, and, therefore, is liable to escape observation, whilst at the same time it may be destroying many of the tiny germinating seedlings.

Treatment consists of dusting with a 2 per cent. nicotine dust, which is procurable from most merchants. As the eggs of the flea may hatch out in a few days, the dusting must be repeated at least every fortnight.

Cut Worms (*Euxoa radians*).—These are caterpillars about 1½ in. in length, which attack plants at night, but during the day bury themselves in the loose earth surrounding the stem. They may do damage in the seedbed, but more frequently are destructive after the transplants have been set out in the field. The stem of the young seedling is severed, thus destroying it, and necessitating replanting.

Treatment should commence a few days before transplanting is anticipated, and consists of distributing poison baits over the field intended for planting. The bait is made up of 50lbs. bran and 1lb. Paris green moistened to a crumbly mass by the addition of sweetened water. The sweet solution may consist of 1lb. of sugar or 1½ pints of molasses dissolved in 1gall. of water. The mixture should be broadcasted over the field at the rate of about 20lbs. (dry weight) per acre, such distributing being done late in the evening, so that the bait may be fresh when the cut worms are active.

Should the field be badly infested, a small ring of poisoned bait may be strewn around each seedling, whilst before a plant is reset the soil should be searched for the destroying

cut worms. They are usually to be found an inch or so below the surface of the soil, and when disturbed assume a curled position. Turkeys or other poultry are useful in checking cut worms, and if turned into infested fields devour many caterpillars.

**Bud Worm (*Heliothis obsoleta*).—**This caterpillar is also known as the bollworm, and, in addition to tobacco, attacks many other types of plants. The moth lays her eggs in the heart of the plant, where they hatch out in the course of a few days. The caterpillars are about 1½ in. long when full grown, and vary in color from pale to dark green with striped bodies. They are very heavy feeders, and quickly eat out the tender portions of the plant, ruining many leaves.

Injury caused by Bud worm.

(U.S.A. Dept. of Agriculture.)

Treatment consists of poisoning and hand picking. The usual poisons are arsenate of lead or Paris green, broken down to a 10 per cent. dust with hydrated lime. This dust is applied to the whole of the plant, paying particular attention to treatment of the bud. A quick method of application is to place the dust in a coarsely woven bag or finely perforated tin, and to shake over each plant.

Hand picking is a tedious job, but is at times necessary.

**Leaf Miner (*Phthorimaea operculella*).—**The parent moth deposits her eggs within the tissue of the leaf or stem, and upon hatching the young caterpillar eats between the two sides of the leaf, leaving the skin intact. As a number may mine on a single leaf, they sometimes do considerable damage. The miner is about ¼ in. long, with brownish head and greenish body. Owing to its method of entry, treatment is very difficult, but dusting as for bud worm appears to be of assistance.

**Stem Borer (*Phthorimaea heliopa*).—**This pest is of the same family as the leaf miner, which it resembles in appearance, but instead of working in the leaves, is situated in the stem. The eggs are frequently laid whilst the plants are still in the seedbed, and the caterpillar eats its way into the stem, thus severely checking the growth of the seedling. The stem swells, and within the swelling the caterpillar may be found.

Treatment is not very effective, and consists of pruning the plant below where the borer is placed, and allowing only one shoot to develop.

## DISEASES.

A source of infection for disease may be the seed, and, therefore, all seed sown should have come from healthy plants and disease-free areas. Should any doubt exist, the seed may be pickled by immersing in a 10 per cent. Formalin solution for 15 minutes. Upon removal the seed must be washed in at least three changes of clean water, and thoroughly dried. The operation should take place shortly before seeding, as after about two months the germination is unreliable.

**Blue Mould (*Peronospora* sp.).**—This is the most serious disease affecting the tobacco crop in the Commonwealth, but, fortunately, has not been extensively reported in South Australia. There appears to be a definite relationship between the nature of the weather and severity of the blue mould attack. Bleak, wet periods, with cold nights and muggy days are conducive to the development and rapid spread of the disease. In Victoria

The underside of a young leaf infected with blue mould.

(N.S.W. Dept. of Agriculture.)

it is reported that seasons in which red rust is bad in the wheat crop are generally bad years for blue mould of tobacco. The first serious outbreak of blue mould in South Australia occurred in 1930, when rusty wheat crops were to be found in many districts. Blue mould particularly attacks seedlings in the nursery, and if weather favorable to the disease is experienced it will spread over the whole of the seedbed in the course of a few days. It makes its appearance in small circular spots on the underside of the leaf, and close examination shows these patches to be covered with a pale-bluish down consisting of the threads and spores of the disease. The spots rapidly increase in size if suitable conditions exist, and the plant dies in a few days. Sometimes plants will apparently recover, but if one is examined it will be found that under the bark the stem is encircled by a ring of black tissue. This ring is situated just above the ground level, and appears to be a bacterial disease associated with blue mould. If plants so affected are set out in the field they may completely recover, but are more likely to wilt off after making a certain amount of growth, or be broken off by comparatively gentle winds. On the other hand, if the plants in the seedbed make renewed growth, and examination, by cutting the stem of a few, shows the black ring to be absent or of faint color, the seedlings may be safely transplanted in the field.

**Treatment.**—No effective treatment has as yet been discovered, but the disease is being investigated by the Council for Scientific and Industrial Research, and the result of their work is awaited with interest by all connected with the tobacco-growing industry. At present treatment must be largely preventative, and aim at improving seedbed conditions, thus allowing plants to escape and also to resist attack. It is known that uniformly warm temperatures are not favorable to the development of the disease, and, therefore, heated seedbeds are sometimes constructed with flue pipes from a furnace at one end, led through the soil at a depth of about a foot from the surface.

Other measures are:—

1. Make provision for several seedings at intervals of a few weeks, in the hope that at least one seeding may escape the critical period.
2. Sterilise and adequately prepare the seedbed to promote the rapid growth of the young plants.
3. Cover and board the beds to protect them from excessive rain and cold.

A young tobacco plant infected with blue mould.

(N.S.W. Dept. of Agriculture).

4. Pay close attention to full ventilation, allowing the young plants plenty of air and sunlight.
5. Water sparingly.

As soon as the seedlings are ready for planting they should be set out in the field without delay, as transplants are rarely seriously attacked unless infested with the disease before removal from the nursery. Should the disease appear in the seedbed, all affected plants must be removed and destroyed whilst the mould may possibly be checked by spraying the remainder with Bordeaux mixture made up of 3lbs. copper sulphate, 2lbs. freshly burnt lime, and 50galls. of water, but success in this connection is by no means assured.

#### SUMMARY.

1. There is ample room for expansion in the tobacco-growing industry, as Australia only produces from 8 to 10 per cent. of its requirements for tobacco.
2. Only light textured, mild smoking, flue-cured leaf is saleable.
3. The production of bright tobacco was first commenced in South Australia in 1920, and appears likely to become an important and profitable crop.

4. In order to supply quality leaf, tobacco must be planted on the lighter and less fertile type of soil in districts reasonably free of frosts, with good summer rainfall and humid conditions.

5. Considerable areas in South Australia appear fairly well suited to tobacco, except for the absence of regular summer rainfall. For this reason growers are strongly recommended to provide means for irrigation.

6. The species of tobacco commonly grown is *Nicotiana tabacum*.

7. There are two types of tobacco, namely, Virginian and Burley. The former is more popular, the chief varieties being Warne, White Stem Orinoco, Hickory Prior. The latter is increasing in popularity for soils of the heavier type, and best varieties are Judy's Pride and Standing Resistant.

8. Tobacco does not thrive in sour soil, and new land should not be immediately planted with this crop.

9. Whilst it is not an exhausting crop, tobacco should be planted in rotation with pasture, such as subterranean clover.

10. Thorough soil preparation is essential.

11. Tobacco requires liberal manuring with phosphoric acid, and usually the addition of nitrogen and potash are of benefit. Applications of up to 10cwts. 45 grade superphosphate or 8cwts. of complete fertiliser have proved economic.

12. The manure may be applied before setting out, at transplanting, or after the plants are established, whilst probably a combination of all three times will produce best results.

13. Particular attention must be given to preparation of the seedbeds.

14. In order to destroy disease spores, injurious pests, &c., the seedbed soil should be sterilised by fire or fumigation.

15. As a safeguard against accident, at least twice or even three times the seedbed area required to provide seedlings for the field should be prepared.

16. One (1) ounce of seed should provide plants for 7 acres of land. 100 square feet of seedbed area are required per acre of land to be planted.

17. The seed must be only lightly buried.

18. The beds should be sheltered by protective coverings, and kept regularly moistened.

19. If plants are too thick in the seedbeds, they should be thinned out to allow for healthy development, and, if backward, may be assisted by the addition of liquid manure.

20. For some time before transplanting the protective coverings should be gradually removed, and the seedlings hardened off.

21. The time of transplanting will vary with the district, and in the Adelaide Hills November appears to be the most suitable month.

22. If possible, choose cool, cloudy weather, and in warmer conditions the young plants should be shaded after setting out.

23. On the average seedlings are spaced about a yard apart in each direction, when approximately 5,000 plants are required per acre.

24. Seedlings may be effectively set out either by hand or transplanting machine, but if the latter is employed the soil should be in a fine state of division, and free of roots, sticks, or other rubbish.

25. Tobacco responds to thorough tillage of the planted field, and whenever weeds or surface crust renders cultivation advisable, the operation should not be delayed.

26. As the summer rainfall in this State is irregular, irrigation water should be available and applied by means of furrows whenever the condition of the plants indicates their requirement for moisture.

27. Irrigation water should not be applied after the topping of the plants.

28. In topping, no leaf of less than about 1ft. in length and 5in. in width is worthy of being left on the plant for harvesting. An average number of leaves left is from eight to 10.

29. Plants usually commence to ripen about four weeks after topping. Heavy topping hastens ripening, and light topping delays ripening.

30. The suckers that spring from the axes of the leaves after topping must be kept rubbed off, or the quality of the leaf is affected.

31. The ripening of the leaves is indicated by characteristic changes in the color, texture, crispness, &c.

32. The plants should have completed their growth by the middle of February to allow for ripening of the leaf in suitable climatic conditions.

33. It is important that the leaf be thoroughly matured, but not over-ripe, before harvesting.

34. The leaf must be picked in suitable weather conditions for best results. Wet or wilted tobacco leaf is not desirable.

35. The method of hanging the leaves in the curing barn is to attach them to sticks by means of tying or threading on projecting wire pins.

36. Curing barns may be built of a variety of materials, but must have special provision for heating and ventilating.

37. The dimensions for most barns in this State are 12ft. by 12ft. by 20ft.

38. A barn of this size is capable of curing leaf from about 5 acres of crop.

39. The operation of flue-curing can only be thoroughly learned by practical experience.

40. The curing process involves three distinct stages, namely, yellowing the leaf, fixing the color, and drying the leaf.

41. For the production of bright colored leaf particular attention must be given to the yellowing process by making sure that the correct shade of color is secured before the temperatures are raised and the next stage commenced.

42. The sponging or condensing of moisture on the leaves is preferable to scalding or reddening, due to too rapid increase in temperature and ventilation.

43. When drying the leaf, the midrib must be thoroughly dried out, otherwise mould is likely to develop in the bulk.

44. Many variations occur in the curing process, according to the condition of the leaf when harvested.

45. On completion of curing the leaves are dry and brittle, and, to avoid damage, must be allowed to absorb moisture before being removed.

46. Upon removal from the barn the leaf is bulked down, during which it passes through a mild ferment and improves in quality.

47. In the preparation of leaves for market tobacco is graded into various classes, according to color, texture, size, and soundness. The highest grade is a lemon-yellow color with light bodied, thin, elastic texture, and large, sound leaf.

48. Green leaf has no value.

49. The graded leaf is made up into small bundle containing from 15 to 20 leaves, called hands.

50. The hands are packed in hessian packages, termed bales, about 3ft. by 1½ft. by 2ft., and weighing approximately 200lbs.

51. The tobacco buyer visits the farm of the grower and submits prices for the leaf submitted.

52. The prices in South Australia range from 3s. 2d. to 6d. per lb., with some leaf rejected.

53. The average yield to-day is probably not more than 4cwts. per acre.

54. With irrigation and added experience the average yield is likely to increase to 6cwts. to 7cwts. per acre.

55. Lucerne flea frequently causes damage in the seedbeds. Treatment consists of dusting with 2 per cent. nicotine dust.

56. Cut worms are at times destructive of seedlings set out in the field. The method of control is poisoning with Paris green and bran baits.

57. Bud worms may devour the heart and tender leaves of tobacco plants. They may be checked by dusting with powder containing 10 per cent. arsenate of lead.

58. Leaf miners and stem borers are difficult to control.

59. Pickling the seed in a 10 per cent. formalin solution for 15 minutes, then washing at least three times in clear water and thoroughly drying, tends to prevent infection by seed-borne diseases.

60. The most serious disease in Australia is blue mould. No method of control has been discovered. Treatment must be largely preventative, consisting of endeavoring to keep the seedbeds in such condition of moisture and temperature as to be unfavorable to the development of the disease.

### Metters Master "Nuoil" Double Geared Windmills, 1931 Pattern.

Manufactured in sizes from 6ft. to 14ft.

Proclaimed by experts to be the most suitable wind mill for Australian requirements—

Simplified automatic governing system—no springs or weights.

Improved design, permitting easy access to all working parts.

Equipped with Replaceable and Interchangeable Bearings of Most Suitable Anti-friction Metal.

Strongest, most reliable, works with lightest breeze, and will pump more water.

Entirely manufactured in South Australia by—

## METTERS LIMITED,

NORTH TERRACE, ADELAIDE  
(near Railway Station).

## THE MARKETING OF EGGS

(WITH SPECIAL REFERENCE TO THE OVERSEAS EXPORT TRADE).

[By C. F. ANDERSON, Government Poultry Expert.]

With the expansion of the poultry industry throughout the Commonwealth and the approach of the coming export season a general review of the egg position, with special reference to South Australia, should not be out of place.

The poultry industry throughout Australia has made very rapid advancement, especially during the last five years, and with more attention being paid to the production of eggs as a sideline on a large number of our farms, the surplus available for export will be greatly increased.

The history of the poultry industry in South Australia and the marketing of eggs, especially up to the last four to five years, has been purely an Australian industry, without any attention being paid to the export of eggs overseas. For a long number of years, principally owing to the fact that eggs on the wheat farms have been produced cheaply, and where poultry have foraged in the fields for a large percentage of their food, these eggs have been exported to the Eastern States, chiefly Sydney, in the form of egg pulp for use by pastrycooks for cake and biscuit making. With the expansion of the industry in the Eastern States, the interstate market for South Australian pulp is being gradually closed, until we have now reached the stage when we are forced to look elsewhere for a market for our pulp.

The only market at the present time is England, with a possibility of small sales being made to Canada. It is, however, doubtful whether we can profitably compete with foreign countries, especially China (which is a very large exporter of egg pulp) on the London market.

There is, however, another view to be taken, and that is whether the export of eggs in the shell can be increased, and if so, whether there is a profitable outlet for them. Statistics prepared by the Department of Markets for the three years ending 1929 show the total imports of eggs into Great Britain and Australia's share of same as follows:—

### *Total Imports into United Kingdom.*

| 1927.<br>Doz. | 1928.<br>Doz. | 1929.<br>Doz. |
|---------------|---------------|---------------|
| 2,028,362,500 | 2,205,540,000 | 2,080,360,000 |

### *Australia's Share.*

| 1927.<br>Doz. | 1928.<br>Doz. | 1929.<br>Doz. |
|---------------|---------------|---------------|
| 1,018,100     | 2,225,000     | 3,126,270     |

For the three years, therefore, Great Britain imported a total of 6,314,262,500 dozen, and Australia only supplied 6,369,370 dozens. It is interesting, however, to note that from 1927 to 1929 Australia's exports of eggs trebled, and is still rapidly increasing. On studying the above figures it seems reasonable to assume that Australia's exports of eggs can be safely increased.

Poultry as a sideline on our wheat farms should be largely extended, for there are several advantages possessed by our farmers. We have in South Australia one of the finest climates in the world for egg production, the feeding costs can be reduced to a minimum for the reason that the bulk of the food necessary for egg production is produced on every farm of the State, in addition to the amount of food the fowls are able to get by foraging in the fields, and again we have some of the best laying stock in our White Leghorns and Black Orpingtons that can be found in any part of the world. In any future extension, however, that takes place it must be kept in mind that the market

for our surplus must be found outside Australia, and in this direction the future of the poultry industry as far as South Australia is concerned depends solely on whether we are able to produce, and, more important, market an egg which will come up to export standard as laid down in the Commonwealth regulations referring to the export of eggs.

The outlet for our exports is in two forms:—

A. Eggs in shell.

B. Egg pulp.

We look, naturally, to the form of export which will be the more profitable, and on studying figures for the last three years, it will be found that export eggs in the shell have returned to the producer a net return of 1s. per dozen, while egg pulp would have returned from 6d. to 6½d. per dozen. In other words, eggs exported as eggs in the shell are worth practically twice as much as eggs exported in the form of pulp. It is safe to assume that as regards egg pulp, it is doubtful whether it can be profitably exported, but for eggs in shell there is every reason to believe that a remunerative return can be obtained. It has been definitely shown during the last five years that eggs can be marketed in South Australia quite suitable for export. In this direction it is interesting to note that last season our egg exports reached the record of 25,000 cases, and the indications are that for this coming season approximately 40,000 cases will be shipped.

The normal export season is from early in July until the end of November, and as this period happens to be our heaviest period of production, we are placed in a very favorable position.

The weakness in the poultry industry from the farmer's viewpoint is the long delay in the time of the eggs being received on the city packing floors from when they are laid. Eggs to be suitable for export should reach the packing floors at least four to five days after being laid. The eggs should be collected at least twice a day, and oftener if possible. The more frequently the eggs are collected the better the opportunity of keeping the eggs clean. For instance, eggs laid in the morning and not collected until evening time are liable to become dirty shelled by the other birds going in and out of the nests. Export regulations demand that all eggs shall be clean shelled. The nests should be cleaned regularly and a plentiful supply of clean sand or shell grit should be provided. Straw is not suitable owing to the fact that the straw often badly stains the shell of the egg, and straw stains are very difficult to remove. The eggs should be packed in either cardboard fillers or clean dry cocky chaff for transport to the city; dirty packing material causes the eggs to become dirty and unsuitable for export.

All surplus male birds should be either penned off separately or marketed. Infertile eggs—that is, eggs produced by unmated hens—will keep under proper storage conditions for weeks, while fertile eggs rapidly lose their quality, especially during the warmer weather.

Special attention should also be paid to the production of full-sized 2oz. eggs and over. The small 1½oz. egg and under threaten to become a serious menace to the poultry industry. It is folly to export a 1½oz. egg 14,000 miles to London, where they come into competition with the small eggs produced by foreign countries. They are a reflection on the ability of our poultry farmers when it is realised that every egg that leaves Australia for England must be branded with the word "Australia." It is not the small 1½oz. egg on which a profitable and lasting export trade is going to be built, but it is the 2oz. egg and over which is going to favorably entrench the Australian eggs on the London market.

To briefly summarise, the requirements for export eggs are:—

1. The full-sized 2oz. egg and over.
2. All eggs to be perfectly clean-shelled.
3. Eggs to arrive at the packing floors not more than five to six days old.
4. Every extra egg exported has a stabilising effect on our local market for the remainder of the year.

## STATE OF SOUTH AUSTRALIA.

### ACREAGE OF CROPS, SEASON 1931-1932.

The Government Statist reports having completed an estimate of the probable acreage either sown or intended to be sown with cereals for the season 1931-1932. This estimate is based on returns received from farmers in each agricultural hundred of the State.

Following the usual practice, further reports will be obtained after all sowing is completed, when the whole of the figures will be reviewed for a further estimate to be issued in September.

#### *Estimated Wheat Acreage.*

| Division.           | Actual,<br>1930-31. | Estimated,<br>1931-32. | Increase. |
|---------------------|---------------------|------------------------|-----------|
| Central .....       | 708,915             | 695,000                | — 13,915  |
| Lower North .....   | 933,983             | 915,000                | — 18,983  |
| Upper North .....   | 358,778             | 390,000                | + 33,222  |
| South-Eastern ..... | 71,984              | 60,000                 | — 11,984  |
| Western .....       | 1,264,450           | 1,175,000              | — 89,450  |
| Murray Mallee ..... | 1,171,103           | 1,065,000              | —106,103  |
| Total State .....   | 4,507,213           | 4,300,000              | —207,213  |

When it is recalled that the area sown last season, 4,507,213 acres, was substantially a record, the decrease of 207,000 acres, or 5 per cent., this season, is insignificant. The increase from 1925-1926 had been continuous and substantial, as follows:—1925-26, 2,750,873 acres; 1926-27, 3,003,667; 1927-28, 3,324,983 acres, 1928-29, 3,775,601 acres; 1929-30, 3,987,310; 1930-31, 4,507,213 acres.

*Barley*.—Actual, 1930-31, 267,369 acres; estimated, 1931-32, 240,000.

*Oats*.—Actual, 1930-31, 519,300 acres; estimated, 1931-32, 522,500.

*Area Fallowed*.—The area fallowed during 1930-31 for the 1931-32 crops was 2,513,000 acres. The substantial increase since 1925-26 is shown as follows:—1925-26, 1,885,753 acres; 1926-27, 2,099,979 acres; 1927-28, 2,169,483 acres; 1928-29, 2,199,231 acres; 1929-30, 2,293,964 acres; and 1930-31, 2,513,000 acres.

*Five Years' Clearing of New Land*.—During the five years to 1929-30 886,381 acres have been cleared in the Western Division, 225,782 during 1929-30; and 725,301 acres in the Murray Mallee Division, 138,233 acres during 1929-30. The total for the whole State is 1,726,258 acres and 392,168 acres for year 1929-30.

## RED COMB EGG ASSOCIATION.

## OFFICIAL SINGLE TEST.

## EGG-LAYING COMPETITION, 1931-32.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1, White Leghorns—141 birds. Section 2, Black Minorca—9 birds. Section 3, Black Orpington—57 birds.

Twelve Months Test. To start on April 1st, 1931.

Section 1.—White Leghorns.

## ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR JULY.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

The splendid rains have given the new season an excellent start, better than we have seen for the past five years; the subsoil should have a good storage to carry the trees through the year and enable them to produce a big crop of fruit. It now remains for us to see that that crop is of high grade.

Pruning should be proceeded with and completed as early as possible, being careful to leave as much wood as we can for fruiting, and also careful to do away with any wood likely to harbor disease, such as broken ends, and so on. Vines should certainly be able to carry more wood than last season. When selecting rods try and get good, healthy wood in such a position that it will be easily handled by those who have to secure it to the supports, and will be safe from the work of the cultivators; clean the vines as much as possible to prevent fungous troubles.

Get all cuttings burned or carted away as soon as practicable.

Destroy all wasting fruits and leave drying racks open to the birds.

Do not allow water to remain stagnant about trees or vines or strawberry beds.

The first chance that offers, try out the practice of using a fungicide to assist in controlling curl leaf, shot hole, scab, &c., using winter strength Bordeaux Mixture, or use bluestone alone; it will not prevent good work if the trees are wet, but rain will spoil its effectiveness.

Finish planting whenever the day is fine enough for the soil to be friable; do not continue the work when the soil is sloppy.

Tomato houses require constant attention if disease is to be controlled. Take out and destroy all sickly plants. Keep the house and the surroundings free from weeds. For cut worms or other caterpillars use arsenate of lead spray or dust, and for white fly use black leaf 40 or nicodust 3 per cent. Drain all excess water from about the houses.

Wet days afford an opportunity to make sure that the spray outfit is ready for service.

Treat vines affected by anthracnose thoroughly and save loss later on; ask for instruction if required.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

### RIVER MURRAY PRUNING COMPETITIONS.

The annual River Murray Pruning Competitions, conducted under the auspices of the Agricultural Bureau, were held in the Government Orchard, Berri, on June 17th, 1931. Mr. E. Leishman (District Horticultural Instructor) acted as judge, and was assisted by Messrs. C. Smith (Renmark) and L. Chapple (Berri). The following tables set out the awards:—

#### *Fruit Trees.*

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on June 24th, there being present Messrs. F. Coleman (Chairman), H. N. Wicks (Vice-Chairman), J. W. Sandford, P. H. Jones, S. Shepherd, A. L. McEwin, P. J. Baily, Professor A. J. Perkins (Director of Agriculture), W. R. Birks (Principal Roseworthy Agricultural College), and H. C. Pritchard (Secretary). Apologies were received from Mr. A. J. Cooke and Dr. A. E. V. Richardson.

**Blue Striped Wool Packs.**—The following resolution was submitted by the Blackheath Branch: "That the Advisory Board take the necessary steps to overcome the objection against color lines in wool packs." It was decided that the Secretary should ascertain from the Stockowners' Association what action had been taken in this matter.

**Young People's Employment Bureau.**—Mr. P. H. Jones was appointed to represent the Board on the Young People's Employment Bureau.

**New Branches.**—Approval was given to the formation of new Branches at Penola (Women's), Belvidere, and Macclesfield, as from August 1st, 1931, and the following gentlemen were entered as foundation members of the latter Branch:—H. Ross, J. Schmidt, E. Mountstephens, W. Whitehouse, T. Lane, J. McGrath, S. Peters, C. Yates, B. Johnson, J. O'Loughlin, F. Pfeiffer, H. McDonald, E. Stecker, L. Boothby, H. Turner, W. Lamshed, H. Rogers, H. Birks, A. Francis, F. Ball, H. Forbes, M. Williamson, J. Kenner, K. Bowen, O. and E. Kuchel.

**Life Members.**—The following names were added to the roll of Life Members of the Agricultural Bureau:—Messrs. T. Ryan (Warcowie), H. W. Nosworthy (Gumeracha), E. Leishman (Murray Bridge), W. P. Foulis (Willowie).

**Record of Services.**—The Secretary was instructed to send a letter expressing the appreciation of the Board of the services of Mr. H. W. Cornish, who has acted as Secretary of the Weavers Branch for a number of years.

**New Members.**—The following names were added to the rolls of existing Branches:—Morchard—E. T. Tilbrook; Mount Gambier—H. Kuhl; Jamestown—F. Parrington. As from August 1st.—Maltee—W. H. Klau; Kelly—P. L. Toole; Mount Barker—Messrs. Miels and Lucie; Parilla Well Women's—Mrs. C. Napper, Miss E. Pahl.

Number of members, 8,537; number of Branches, 308.

**Retirement of Members.**—The following members retire on June 30th in accordance with the constitution of the Board:—Messrs. G. Jeffrey, A. L. McEwin, J. W. Sandford, R. H. Martin, S. Shepherd, and Dr. A. E. V. Richardson, but are eligible for re-appointment by the Hon. the Minister.

**In Committee.**—Other items were taken in committee.

### **ROSEWORTHY AGRICULTURAL COLLEGE.**

## **PIGS FOR SALE**

Pure Berkshires and a few Pure Tamworths.

**PRICES—FROM TWO GUINEAS.**

Full particulars from The Principal.

**DAIRY AND FARM PRODUCE MARKETS.**

A. W. SANDFORD & Co., LIMITED, reported on July 1st, 1931:—

**BUTTER.**—The outlook for the present season is the most promising for very many years past, and the good general rains received throughout the past month will have a very beneficial effect, not only on the growing pastures, but will recoup the subsoils after the severe drain made upon them during the past few years. Production of butter is steadily improving, and shipments are going forward regularly overseas. Providing the markets continue favorable, the outlook for the dairying industry is decidedly hopeful. There was very little fluctuation in values during this month, although store and collectors' butters eased somewhat, owing to the fact that there is only a limited demand in the Commonwealth for such, and this is a line which cannot be exported with profit. Present quotations are:—Choice creamery fresh butter, in bulk, 1s. 3½d. Prints and delivery extra. Second and third grades, 1s. 1½d. (These prices are subject to the stabilisation levies.) Well-conditioned store and collectors', 9d. to 10d.

**EGGS.**—As usual at this time of the year, production is showing an increase, and values eased. The outlook for a heavy export season seems assured, and arrangements are being made for shipments to go forward towards the end of this month, which will be followed by regular consignments afterwards. As all the States of the Commonwealth are anticipating a very heavy surplus, the only outlet is to London; but values will have to recede considerably before shipments are payable, as London market is considerably easier than last year. Present prices are:—Ordinary country eggs, fresh hen, 9d. per dozen; duck, 10d. per dozen; selected, tested, and infertile, higher.

**CHEESE.**—The supplies of cheese from the South-East have only been small throughout the month, but this is usual during the cold period of the year, and a large increase in production cannot be looked for for a month or two yet. Rates are steady. New makes, large to loaf, 8½d. to 8¾d. per lb.; semi-matured and matured, 10d. to 11d. per lb.

**ALMONDS.**—Supplies of almonds sent in have been fairly extensive, but a good steady demand was experienced throughout, both local and interstate purchasers operating. The call for kernels has been exceptionally brisk, and rates firmed, present quotations being:—Brandis, 7d. to 7½d.; mixed softshells, 6d. to 6½d.; hardshells, 3½d. to 3¾d.; kernels, 1s. 8d. per lb.

**HONEY.**—Steady sale for prime quality honey continued throughout the month under review, but lower grades were again neglected. Sales to Western Australia were prevented because of the regulations there in connection with "foul brood," and orders had to be turned down because of this. Rates are steady. Prime clear extracted, in liquid condition, 3½d. to 3¾d.; best quality candied lots, 2½d. to 3½d.; second grade, 1½d. to 2d. per lb.

**BEEFWAX.**—In moderate supplies. Demand steady; 1s. 2d. to 1s. 2½d. per lb., according to sample.

**BACON.**—Considering the lower purchasing power of the people generally, the demand for bacon kept up well. This is accounted for largely by the fact that prices are quite reasonable, as compared with other meats. Ample supplies were marketed each week by the factories, so that there was no need for importations from the other States. Best local sides, 9d. to 9½d.; best local factory cured middles, 9d. to 9½d.; large, 8½d.; local rolls, 8d. to 8½d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 1d.; local hams, 10d. to 10½d.; cooked, 1s. to 1s. 1d.; "Sugar Cane" brand lard, in packets 11d., in bulk 10d., per lb.; local prints, 9d. per lb.

**LIVE POULTRY.**—The catalogues of live poultry submitted throughout the month were again fairly representative, but poulterers regularly attended the sales and purchased freely. Good clearances were effected from week to week, but the quality of many of the birds submitted were only light to medium breeds, and the really first-class stock have been somewhat short of requirements. Prime roosters, 3s. to 4s. 1d.; extra heavy roosters to 4s. 6d.; nice-conditioned cockerels, 2s. 6d. to 2s. 11d.; fair-conditioned cockerels, 2s. to 2s. 5d.; chickens lower; heavyweight hens, 2s. 9d. to 4s.; medium hens, 2s. 3d. to 2s. 8d.; light hens, 1s. 8d. to 2s. 2d.; couple of pens of weedy sorts lower. Geese, 3s. 6d. to 5s.; prime young Muscovy drakes, 3s. 3d. to 4s. 6d.; Muscovy ducks, 2s. 3d. to 3s.; ordinary ducks, 1s. 9d. to 2s. 2d.; ducklings lower. Turkeys, good to prime condition, 8d. to 9½d. per lb., live weight; turkeys, fair condition, 6½d. to 7½d. per lb., live weight; turkeys, fattening sorts, lower. Pigeons, 4d. to 6d. each.

**POTATOES.**—Local, 4s. to 4s. 6d. per cwt.

**ONIONS.**—Brown, 5s. 6d. to 6s. per cwt.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month and to the end of June, 1931, also the average precipitation to the end of June and the average annual rainfall.

| Station.                   | For June, 1931. | To end June. | Av'ge to end June. | Av'ge Annual Rain-fall. | Station.               | For June, 1931. | To end June. | Av'ge to end June. | Av'ge Annual Rain-fall. |

\* No report received during the month of June.

† Held over.

R In recess.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS. WOMEN'S BRANCHES.

#### BELALIE.

June 9th.—Present: 20 numbers and 26 visitors.

The meeting was devoted to a competition for the best decorated dinner table, display of work done by pupils of the dressmaking and art needlework classes, hessian work by Miss Phyllis Moore, and an exhibition of work—ancient and modern—by hand, loom, or machine. The prizes (donated by the President) for the best decorated table were won by Mrs. E. J. Swann first, and Mrs. L. R. Clarke second. There was a good display of dressmaking and art needlework, and a very interesting exhibit of old and valuable work. This included cushion covers and d'oyleys, table covers and macrame work, ancient point lace and modern wool work. It was decided to form a depot for the outback relief in connection with this Branch. Miss Mitchell read extracts from Miss Campbell's article on Hessian in the Home, and Miss P. Moore's work used for demonstration. Musical items were rendered by Miss L. Clarke and Mesdames Symonds, Price, Swann, and Clarke. (Secretary, Mrs. E. Orchard, Jamestown.)

#### MILLICENT.

May 15th.—Present: 14 members.

**ECONOMIES IN THE HOME.**—Mrs. Redman read a paper on this subject. *Mutton Flaps.*—These can be bought very cheaply. Buy a number of flaps and boil them, adding a little salt to the water. When cooked, put aside until next day. The water in which they are boiled makes excellent stock for soup or gravy. It should be allowed to stand all night, and in the morning the fat should be carefully removed, melted down, and poured into a jar. This fat is excellent for frying or other purposes. The fat should also be removed from the mutton flaps, and that, too, can be rendered down in the oven to provide more dripping. The meat in the flaps can be minced to make curry, or, with the addition of minced bacon, onion, and bread crumbs, it can be made into a very appetising pie. The minced mutton, flavored with pepper, salt, and onion, can also be used for meat turnovers. The pastry for these being made of mashed potatoes mixed with flour, an egg, and a little milk, to make a firm dough. Dripping is used for cakes and pastry; and in making cakes, if cream of tartar is added when the dripping and sugar are being beaten together it helps to disguise the taste of the dripping. *Pot Cleaner.*—A split peg makes an admirable pot cleaner. It removes porridge and milk most effectively, and the end of the peg, being soft and rounded, does not scratch the saucepan. *Use for Eggshells.*—Eggshells are most useful on washing day. Save and crush them and put them into the copper with the clothes, and they will help to make them beautifully white. *Quilts.*—A white quilt which is wearing out will last much longer if lined with an old sheet, especially if the sheet be torn down the middle and the side edges stitched together, bringing the less worn parts to the centre, where the wear is heaviest. Face towels should be turned ends to middle when half worn. Tablecloths, when wearing thin, may have their lives lengthened by cutting off 2in. or 3in. from one side and one end. This will bring the stronger parts to the edges of the table where the wear is the greatest. *Use for Candle Ends.*—These may be saved by putting a penny over the top of the candlestick, or putting a cork in the hole. The candle end resting on this may be burnt right down. Candle ends, too, if melted and mixed with a generous quantity of turpentine or kerosene, make good furniture polish. Odd bits of soap should be saved, put into a saucepan or billycan, and melted down with a little water. This is easily done by standing the vessel containing them in a larger vessel of boiling water and leaving it for a few hours where the water will boil gently. When melted, stir well and pour it into a shallow dish to set. Mrs. Cassell supplied the following recipes:—*Economical*

*Pudding*.—1 cup of flour, 2 tablespoonfuls sugar, 1 tablespoonful jam, 1 small table-spoonful dripping, and a few raisins,  $\frac{1}{2}$  teaspoonful carbonate soda dissolved in a small cup of milk. Mix dry ingredients together and add milk and soda. Steam for two hours. *Home-made Soap*.—5lbs. clear unsalted fat, 5 quarts water, 1lb. resin, 1lb. caustic soda which has been dissolved in 2 quarts of water. Boil all together slowly for half an hour. Lift from the fire and leave stand until next day, when cut into pieces.

Mrs. H. Hutchesson read a paper and brought two recipes for meatless dinners. *Cheese Cutlets*.—1 cupful of mashed potatoes, the same of boiled rice,  $\frac{1}{2}$  a cup of grated cheese,  $\frac{1}{2}$  teaspoonful of dry mustard, 1 tablespoonful of milk, and a little salt. Mix ingredients together, mix mustard to a paste with milk. Form into cutlets, roll in flour. Put dripping in baking tin, when hot, put in the cutlets. Brown them on both sides. Pile on hot dish and serve with tomato sauce. *Meatless Sausage*.— $\frac{1}{2}$ lb. haricot beans,  $\frac{1}{2}$ lb. bread crumbs,  $\frac{1}{2}$ oz. butter, 1 egg, pinch of herbs, salt and pepper to taste, 1 small onion if liked. Soak beans overnight. Boil till tender, strain, add butter, herbs, egg, salt and pepper. Mix well, roll out, and fry a nice brown. The fat should boil before putting in the sausage. The water in which the beans cooked is suitable for soup or gravy.

Mrs. Oberlander forwarded the following hints:—When scrambling eggs add 1 table-spoonful of fine bread crumbs and 1 tablespoonful milk to every beaten egg. Season with salt and pepper and cook in the usual way. A little vinegar added to stewing prunes greatly improves the flavor and lessens the quantity of sugar required.

Mrs. Varcoe read the following paper:—"Small Economies in the Home are Well Worth Practising." In a well-managed kitchen there should be very little waste. The careful housewife can practise many economies in the kitchen without in any way lessening the food value of the meals she prepares. If any pieces of cake have become too old and dry to put on the table, use them to make puddings. Soak in cold water, then squeeze out the water and crumble the cake in a piedish. Beat up with an egg, a little sugar, and milk, add a few currants or other fruit, and any flavoring desired. Bake in oven the same as a custard. Or soak the cake, squeeze dry, take 1 cupful of S.R. flour to 2 cupfuls of cake crumbs, 1 cupful raisins, 1 tablespoonful jam,  $\frac{1}{2}$  cupful sugar, 1 tablespoonful dripping or butter. Mix together, dissolve  $\frac{1}{2}$  teaspoonful carbonate soda in a little milk and mix. Steam for two hours. Stale pieces of bread can be toasted in the oven until brown and crisp, then crushed or put through the mincer, and stored in tins to be used for thickening gravies and stews, or for making puddings. Cold mutton or beef can be minced and made into dry hash or rissoles. *Dry Hash* is made with minced cooked meat, mashed potatoes, and 1 onion cut up small. Add a cup of gravy, or stock if not available. Use a cup of water and 1 tablespoonful of Worcester or tomato sauce. Mix all well together. Put in piedish and cover with egg and breadcrumbs. Bake in slow oven for about one hour. *Cold Meat Rissoles*.—2 cupfuls minced meat, onion cut up small, about half as much boiled rice as meat, 1 egg, 2 tablespoonfuls flour, pepper and salt to taste. Mix well together and fry in hot fat. Serve with mashed potatoes. Other little economies are making serviettes out of the good pieces of worn tablecloths. The worn pieces can be used for cleaning windows or for dusters. A double-bed sheet, when worn thin in the middle, can be made into a serviceable single sheet by cutting a strip out of the centre, sewing the selvages together and hemming the sides. A good plan with the men's trousers is to sew a patch inside as soon as you notice the thin place. It will then take longer for the hole to appear, and when it does it is easy to turn the edges in and sew down to the patch already in place. Darn socks and stockings before the hole appears. I have saved a lot of trouble sewing on buttons by placing a small button at the back of the larger one. This plan is particularly good when sewing brace buttons on trousers. Sew the two buttons on together and they will stop there as long as the pants last. (Secretary, Mrs. W. Varcoe.)

#### PARILLA WELL.

May 19th.—Present: 19 members.

*JELLY MAKING*.—Mrs. Simpson read the following paper:—*Apple Jelly*.—Cut up under-ripe fruit, seeds and skins, cover with water and boil until soft. Strain through jelly bag, and to each cup of juice add 1 cup of sugar and boil for half an hour, or until it sets. Test a little on a plate. A few cloves give a nice flavor. *Quince Jelly* is made just the same; but another recipe, which is more economical, is as follows:—6lbs. quinces, 6 pints of water, 6lbs. of sugar. Boil all together without cutting quinces for four hours, take out quinces and pot the juice. The quinces can be served for dessert with cream or custard. The quinces must be rather green to give the best results. *Lemon Jelly*.—First day—cut lemons into slices, to each 1lb. of fruit add 1 quart of water and let stand 24 hours. Second day—boil 20 minutes and stand as

before. Third day—boil pulp and strain. To every cup of juice add 1 cup of sugar and boil from 20 to 30 minutes. *Citron Marmalade*.—Slice fruit very thinly, to every pound of fruit allow 5 cups of water, let stand over night, then boil for 20 minutes and let stand another night. Weigh the pulp, and to each pound of pulp allow 1½ lbs. of sugar, boil one hour. When boiling strain off the juice and boil separately for jelly. The Secretary then read the article, "The Uses of Hessian in the Home." (Secretary, Mrs. S. Burford).

#### PARRAKIE.

April 28th.—Present: 14 members.

**HINTS FOR JAM-MAKING AND JAM RECIPES.**—Mrs. Watts contributed the following paper:—It has been found that if the amount of sugar per pound of jam is up to a certain amount that the jam will keep well; if over this amount the jam will crystallise. If, on the other hand, the proportion of sugar is not large enough, the jam is liable to ferment. In making most jams, ½ lb. sugar to 1 lb. fruit is sufficient. In cooking jam I find it best to boil briskly, but one must be careful to stir well to keep it from burning. A good plan is to grease the inside of the pan with a little butter to prevent burning. *Dried Apricot Jam*.—1 lb. fruit, 3 lbs. sugar, and 5 pints water. Soak apricots over night and boil for one hour. *Quince Honey*.—Five large or seven small quinces, 5 lbs. sugar, 1 pint water. Pare, core, and mince quinces, boil sugar and water for one hour, add minced quinces, and boil for 1½ hours. *Quince and Melon Jam*.—10 lbs. melon, 6 lbs. quinces, 12 lbs. sugar. Cut up melon into slices, sprinkle with a few pounds of sugar, and stand over night. Boil for one hour. Pare and cut up quinces, stew for one hour, separate from melon, in some of the melon syrup. Then place melon and quinces together with remainder of sugar and boil for 2½ hours. When making apricot jam it is best not to put sugar on the fruit over night. Stone apricots, put into the pan, add one cup of water, and boil until fruit has boiled to a mash. Then add sugar. *Marmalade*.—4 lbs. Poorman oranges, 12 lbs. sugar, 16 cups water. Slice oranges thinly, put into pan, then measure 16 cups of water, pour on the cut fruit, and allow it to stand all night, then boil for half an hour. Add 12 lbs. sugar, and boil hard for another half-hour. Do not forget to boil just after the sugar has been added, otherwise the marmalade will not jelly. (Secretary, Mrs. M. Cabot.)

#### WARCOWIE.

May 26th.—Present: Seven members and five visitors.

**SOAP MAKING.**—The Secretary, Mrs. A. Crossman, read the following paper:—"The recipe I use makes 18 lbs. of soap. This costs about 2s. 8d., and as the cheapest soap costs about 8s. this represents a saving of 5s. 4d. Ingredients—6 lbs. fat, 2 galls. water, 1 lb. resin, 1 lb. tin caustic soda, 2 ozs. borax, and ½ lb. ammonia. Method—Boil fat and water together, add crushed resin and borax, bring to a boil again, then take off fire and add caustic soda. This must be done carefully, because caustic burns very severely if it touches the skin. It is best to set the bucket of soap somewhere out of the breeze, and then add the caustic in small quantities, just a few spoonful at a time. The caustic causes the mixture to boil very furiously, and if too much caustic is added at a time it will boil over. Put the bucket back on the stove and boil slowly for 2½ hours, stirring it now and then. Do not have too big a fire or it will boil over. When boiled enough, take off the fire for a while, say half an hour, and then stir in ammonia dissolved in 1 pint of boiling water. It is not necessary to go to the bother of pouring into moulds. I use a bucket that the handle will slip out of, and I leave the soap in the bucket for a day or more until it is set, then take the handle out of the bucket and turn the soap out in a block. This I leave for another couple of days, and then cut up the soap into bars or pieces and pack them in a box and allow them to dry for a month or more, when it is ready for use. Always make a fresh supply before the previous lot has been used out, so that it has a chance to dry. This soap lathers as good as most shop bought soap I have used, and, providing one is careful with the caustic it is not a dangerous task." Secretary, Mrs. A. P. Crossman.

#### WASLEYS.

June 4th.—Present: 27 members.

**THE FLOWER GARDEN.**—Mrs. V. Currie read the following paper:—"In a flower garden one can spend spare time to advantage, and in course of time will bring much pleasure and a return of flowers which will repay for work done. Practically every home can have a garden, especially in this district, where a supply of water is available, and with very little expense incurred the most humble home may be beautified by a garden, however small it may be. *The Layout*.—First draw a plan of the garden that will make an appropriate setting to the front of the home, taking into consideration the amount of time at your disposal for the working of it, &c., and arrange the size of

flower beds accordingly. Lawns may take up quite a large area, and will also add to the appearance. The Malt lawn needs much more attention than Buffalo grass, though when kept trimmed makes a very fine one, and one that is green all the year. A palm can be planted in the centre, if so desired, and for this purpose I suggest *Chamaerops humilis*. It is of dwarf habit, not growing more than 5ft. to 6ft. in height, is of a bushy nature, and ideal for the small garden. Not only lay out the garden for small flower beds and lawns, but leave a space on one side for the planting of a few shrubs, and along with these can be planted a mixture of perennials as well as annuals. Having laid out the garden, border each bed with jarrah edging 1in. thick by 4in. deep. Around the lawn it is advisable to have it 6in. deep. With shallow edging the grass is likely to go under it and come up either in the flower beds or the paths. Choose a suitable hedge for the front, it will not only enhance the appearance, but shelter the growing plants from all weather. The *Coprosma* makes an excellent hedge for a small garden, it has bright green shining foliage, is almost dust proof, and always looks clean and bright. This hedge is very healthy, rarely dies out, and requires very little water. Plants should be staked and allowed to grow at the top until they reach the desired height, but should be constantly clipped at the sides. The clipping assists them in making upward growth. A few roses must be included. I suggest planting one in the centre of each of the small beds intended for the annuals. June and July are generally accepted as the best months for planting roses—they are then at their most dormant period—but can be carried on until the end of August. They thrive best in open spaces, where they receive plenty of sunshine. Plants grown in shady and sheltered positions are liable to mildew and black spot. Pruning of all roses should be completed during July, for if pruned too early the new growth will start and is likely to be damaged by frosts. April and May are the best months for planting shrubs, before cold weather sets in. Flowering shrubs are some of the most satisfactory plants grown in a garden. They give a dignity to it, and once established are very little trouble, and do not require much water. Many of them produce very beautiful flowers, and, if a careful selection is made, can be had in flower all the year round. The deciduous varieties are the most beautiful. One is the *Weigela rosea*, this is one of the most beautiful of the spring flowering shrubs, covering its branches with clusters of pale-pink tubular-shaped flowers. It should be planted in a well sheltered position on the plains. Another is the Guelder rose, or Snow Ball Bush. This is a very handsome shrub and worthy of a place in any garden, although seldom seen. When in flower the bush is covered with great balls of snow-white blooms, and makes a fine sight. All shrubs should be pruned immediately after flowering; one cannot go wrong if this practice is followed with all varieties. Most shrubs can be pruned to regulate the growth to a certain extent. The Blue Iris *Stylosa* has become one of the most popular winter flowers, flowering, as it does, when other flowers are scarce. During April and May the long leaves should be cut back to within a couple of inches above the crown and then given a dressing of lime to kill slugs and snails, which are very fond of the flowers. Follow this by a good watering, and this treatment will result in a wealth of bloom that make a pretty garden show. If wanted for decorating purposes, pick the flowers in the pencil stage, and they will last much longer. In April prepare beds for spring flowering annuals, and clear away summer growths. The beds should then be limed and roughly dug, and sprinkled liberally with lime again. They should be left for a fortnight to be sweetened by the sun and air. This exposure of the soil in a roughly broken up condition is most important, and without it one cannot expect good results. The use of lime can be overdone unless it be accompanied by liberal manuring. For average conditions I recommend liming every other year. After the fortnight has elapsed water well and dig several times, until the soil is broken to a nice, even tilth. Then give a liberal dressing of stable manure, fork in lightly, rake evenly and remove all lumps. The beds are then ready for the planting of young seedlings, which have been previously raised in pans or boxes. More satisfaction is obtained in raising your own plants than buying them from the nursery. It is advantageous to be able to transplant them quickly from the seed boxes to where they are to be grown, especially during summer, when great precaution needs to be taken only to transplant when a cool change springs up or on a dull day. After planting, water well, not overhead with a hose, but fill a bucket with water and with a dipper or wateringcan pour gently around each plant. During the growing period keep the soil well cultivated. Keeping the surface loosened will encourage rapid growth. As the plants come into bloom, give them a little weak liquid manure once a week. Neutral sulphate of ammonia makes an excellent stimulant for this purpose, using a level teaspoonful to 1gall. of water. Do not exceed this strength, and do not use it more frequently than once a week. The flowers will be much larger and of brighter, richer color than if it were not used. Make sure the ground is moist before applying liquid manure of any kind. Where any patches of clover exists in lawns, rub sulphate of ammonia well into them. It must be used in a dry state and

allowed to remain dry for a few hours. It will cause the clover to turn black, and although the grass will have a scorched appearance, it will come through again without any difficulty. The clover will not reappear. In a small garden it is easier to plant and to plan out the garden if the plants are massed. In doing this the effect will be far better than any mixed lot of flowers. Plant the mixed varieties in the border with a few shrubs. It is not suggested that in all cases only one variety should be grown in a bed, for some of the best results are secured when good contrasts of color are effected. For example, last summer I planted beds of Rosy Morn Petunias with a double row of Blue Ageratum around the edges of each. These made a most brilliant show that lasted for months. The winter previous I had beds of Iceland Poppies bordered with Papilio Blue Violas, and there are many other varieties that could be planted likewise. It is not wise to plant the same kind of flower two seasons following in the same beds. The Blue Brachycome (Swan River Daisy) is very suitable for bedding purposes, is of dwarf habit—growing 6in. high, and covers itself in spring with Cineraria-like flowers. Another interesting and pretty plant is the Night Scented Stock (*Matthiola bicornis*). This grows about 12in. high and has flowers similar to the single stock, only very tiny, and of a light lilac shade. The flower closes in the day time and opens only at night, and the perfume is delightful. It is also a spring flowering annual. Iceland Poppies are the most useful of all winter flowers for indoor decoration. There has been a great improvement in them during the last few years. First, the old varieties were superseded by the Sunbeam strain, which included tangerine and lemon shades, then came the Coonara Pinks—a mixture of pinks and other shades, and now Rose Lustre has made its appearance in the last few years. It is no doubt the finest and richest colored Pink Poppy that has yet been introduced. It is unequalled for those desiring pink flowers. At the end of September or beginning of October it is time to sow seed for the raising of summer annuals. Generally speaking, summer annuals are very much easier to raise from seed than many spring flowering varieties. The weather is mild and warm, and seeds germinate well and quickly. Sow in shallow pans and cover seed with a light sandy soil with a little manure sprinkled on top. This will help to keep the surface from drying too quickly. The best method for watering is to place the pans of seed in a larger one, containing 3in. to 4in. of water,

and allow them to stand until the dampness comes to the surface. There is then no fear of washing fine seed, such as *Petunia*, &c., away. The earth will also hold the moisture longer, and results will amply repay for the trouble. During summer hot and squally weather can be expected, so that one must consider those plants best adapted to such conditions and choose accordingly. Keep to heat-resisting ones, such as *Petunias*, *Phlox*, *Ageratum*, *Zinnias*, &c. Get summer seedlings planted out during the first and second week in December if possible. After planting, water well, and cover the surface with a thick mulch of either stable manure or straw. It will then be only necessary to water once a week, and plants will stand up to the hottest of days under such conditions. There are so many beautiful summer annuals to choose from that it should not be difficult to make the garden gay during that period. *Zinnia linearis* is ideal for growing as a border to a mixed flower bed, and looks well in masses. It is a dwarf grower, having small narrow leaves. The plants cover themselves with tiny single deep-orange flowers, similar to small French Marigolds. The plants keep in flower for months, and one never notices the withered blooms. *Amaranthus tricolor* grown in a mixed border makes a gorgeous show with its striking foliage in green, yellow, and crimson shades. The Miniature Sunflower is another favorite for the border, and will provide a wealth of blooms for cutting as well as a fine garden show. The Miniature Red Hybrids are particularly good for decorating purposes. Klondyke Cosmos should not be overlooked. The foliage is beautiful, and they make handsome garden specimens, requiring some space to show to advantage; 4ft. between each plant is not too much. The flowers are orange, and follow other Cosmos varieties, flowering in late autumn. *Zinnias* are hardy, and make a brilliant show. The Giant strain are particularly fine, having very large flowers. When about 6in. high nip out the centre of plants to encourage them to branch out. This also applies to *Phlox* and *Petunias*. These should be grown in masses to get best effects. Asters are a much admired annual for their richness of coloring, beauty of form, and profusion of bloom. The Giant Crego is the finest type to be had, and looks best when grown in mixed colors. They do best in rich, deep, light soil, and are much benefited by mulching with manure. I would like to draw your attention to a very fine ornamental grass, *Tricholona rosea*, that covers itself with fluffy copper-pink seed-heads. It is excellent for mixing with floral decorations. November is the time for the sowing of the seed." (Secretary, Mrs. M. Wilson.)

## SOUTH-EAST DISTRICT.

### RENDELSHAM.

May 2nd.—Present: 10 members and five visitors.

**POULTRY AS A SIDELINE.**—The following paper was contributed by Mr. W. Smith:—"Many farmers if they knew the profits derived from poultry farming, when correctly conducted, would be astounded. When I suggested growing wheat for poultry only, doubt was expressed as to its practicability. Had those people accepted my proposition and used their wheat for poultry raising, they would have received at the rate of 10s. per bushel for their wheat instead of approximately 1s. 9d., which figure does not include bags or carting, two very considerable items in the cost of production. Referring to the above, I do not include those who grow wheat exclusively, but to the average mixed farm in this district. The following figures will give some indication of the value of the poultry industry. For the year ending June, 1930, the value of the industry on present day values was £950,542. The number of poultry in the State as on June 30th, 1930, was: Fowls 1,552,760, ducks 50,102, geese 16,555, turkeys 46,401, a total of 1,665,818 head. These figures offer more room for thought in the direction of food consumed. It can be taken as a reasonable basis that each head of poultry consumes 40zs. of wheat per day, whether in the form of wheat or bran or pollard; this is equivalent to approximately 2,500,000bush. of wheat per year. The average consumption of wheat per fowl can be taken as 1½bush. per year, equal at present day values in this district

to 2s. 7½d. The average production of a high-class fowl is 12 dozen eggs per annum. Taking the present price offering at the local store, as an average for the year, at 10d. per dozen, it would show a return of 10s. for 2s. 7½d. worth of wheat. These figures are fairly reasonable, and give an insight into the value of poultry if reasonably tended and cared for. Very few primary industries can show such high profits. The number of eggs exported from Australia for the past season up to December, 1930, was nearly 200,000 cases of eggs, each containing 30 dozen. South Australia's share of this total was 25,000 cases, valued at £50,000. The total value of exported eggs for Australia was £430,000. South Australia also has a large interstate export trade of eggs in the shell, and egg pulp, estimated at £150,000 per year. If all other primary industries could show such handsome returns, farmers in Australia would be in a better position to-day. If a farmer wishes to patronise State industries, everything necessary to equip a poultry run can be produced in our own State and purchased at reasonable prices. This is an ideal district for rearing runner ducks. We can also grow every kind of food necessary at a very reasonable cost for their upkeep. Even rabbits can play a very important part in duck egg production. Meat is a very necessary part of a duck's diet if maximum results are to be obtained. I usually boil about 20 rabbits per day for my poultry. This is supplemented with unlimited quantities of green food, the birds having a free run in a large patch of chow moellier and mangolds. They also receive approximately 40zs. of wheat per day per bird. The poultry benefit greatly by having a free run in the green feed; they can always find it fresh and appetising, and nothing is wasted. The next most important item is water. Too often sick birds are noticed on farms, and this is not to be wondered at when one notices the filthy water they are given to drink, out of any rusty tins or dishes, perhaps filled a month before. So long as these receptacles have water in them, no matter how dirty, the owner does not trouble to refill nor cleanse them. They are usually left out in the blazing sun. On many farms the birds are allowed to fend for themselves in the matter of housing, and they usually make the machinery sheds their roosting place; then when a machine is needed the poultry is blamed for the damage. In this district the cost of housing is trifling. It is possible to procure the timber for the cutting, and the thatch for the cutting. I prefer cutting grass or tussock for roofing, as it is much cooler in summer and warmer in winter than iron, and, so far as I have observed, does not harbor vermin. My run is built on a dry shelly bank, so that the shellgrit problem is solved naturally. The green feed grows within 50 yards of the run. Only the very young birds need the green feed plucked and carried to them, which is done every evening, scattering it under a thatched shed to prevent it shrivelling too rapidly when the sun gets on it. The water also is always under a thatched shed. I fill the dishes every morning and night, after flushing them with a solution of bluestone to minimise disease. I attribute the good health of my poultry to the use of bluestone. I also have a pond under a thatched shed for the use of the ducks. This I usually clean out once a day, and refill with fresh water to which is added a kerosene bucketful of bluestone solution: about 20zs. bluestone to a 4gall. bucket. I usually put 10 to 12 buckets of water in the pond. If I omit the bluestone, the water has a strong smell. The ducks make much use of the pond in hot weather, and the labor of making it has been amply repaid. Very few losses of poultry from hawks are experienced, chiefly because there are a number of tussocks growing about the run. One warning cry from the male bird, and not a chicken is to be seen. Even the smallest will run for a tussock. The tussocks also act as shelter in hot weather, the poultry often preferring them to the shed. Occasionally crows are troublesome. In such a case I fix an egg to the plate of a strong rabbit-trap and cover all but the egg with straw. The crow is usually in the trap next morning. Place the trap on a shed where the poultry cannot reach it. Farmers who knowingly sell bad eggs should consider the effect those eggs have on the price of eggs in Adelaide and the local market, and they would find that it reduces prices to a marked degree. One has only to observe the difference in the price of guaranteed fresh eggs to those usually classed as 'collectors lots.' I consider that the storekeeper or collector should instal a testing machine. He would quickly discover those marketing rotten eggs. Incidentally, the honest poultrykeeper would also benefit by an increase in price for eggs that were known to be fresh." (Secretary, Mr. F. White.)

**PIG BREEDING AND RAISING.**—The following paper was read by Mr. G. Bird:—"First select a good breeding sow and mate her with a boar of a breed suitable to get best breed of pigs for fattening purposes. I favor the Berkshire-Tamworth cross. It produces pigs which are quick growers and makes an ideal bacon carcass. It is also advisable, when starting pig breeding, to buy some good suckers and keep them until they are about five months old, and then pick out the young sows that will make good mothers and mate them with the boar. Always give the young sows the best attention. Do not

over feed them, but give a change of food; this will keep them fresh and healthy, but not too fat. Under no conditions must they have boiled or raw meat, as it tends to make them eat their young. A good breeding sow should rear at least from eight to 12 young pigs if properly fed and cared for. A sow should have plenty of exercise. Provide for the sows a small paddock, about a quarter of an acre, with a good, warm shed on it. With a paddock of this size, three sows can be run, but always put them in a sty by themselves about a fortnight before farrowing. Also provide plenty of bedding a week or so before farrowing, for if the sow is a good mother she will prepare her own bed and is not likely to smother her young. It is also a good plan, when the suckers are about three weeks old, to make a small place for them so that they can leave their mother and learn to drink by themselves. This will not be such a strain on the mother pig, who has to rear 10 or 12 young pigs for six or seven weeks. Also the suckers that have learnt to feed themselves go straight ahead after weaning. *Fattening Pigs*—To fatten suckers I give them about four weeks in a sty fed on milk and grain, and then one week on milk and water, and also grain. I then turn them into another sty, about twice as large, and feed only on water and grain fed from a self-feeder. By mixing the water with the milk it is much better than putting them on to water straight, as very often a pig which has been well cared for when a sucker does not take to water unless very thirsty. A pig does much better if there is always drink in the trough, especially if fed on grain. After feeding on grain and water for about eight weeks, a pig has grown enough to top up for market. Four weeks on milk and grain, after feeding on grain and water, should be sufficient to produce a good bacon pig of about 120lbs. dressed weight. Good bacon is made from well cared for suckers, given a good start, and then allowed to grow before topping off. A pig should be at least six months old when dressing 120lbs. Another good point is that by giving a pig time to grow it does not lose so much weight when travelling to market. After giving a sucker a good start off, have a paddock of green feed. The best green feed I have grown is rape and rye mixed. Turn the pigs into the green feed, and all they require is plenty of good, clean water to drink, and very little grain. A pig about three months old, turned into a paddock, will grow well and keep healthy and fatten very quickly when shut up in a sty. The only thing about this method of feeding is that it takes about a month longer to get them on the market, but it pays because it saves so much hand feeding, and they also make very good bacon pigs." Discussing the paper, Mr. Bird favored sour milk instead of fresh milk for feeding to pigs. He also thought that crushed barley was far better than whole barley. Mr. Edgecumbe found that pigs did well on boiled potatoes with a little crushed barley mixed with them. (Secretary, Mr. H. Kennedy.)

## UPPER-NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

APPILA (Average annual rainfall, 14.69in.).

May 1st.—Present: Seven members.

**CARE OF THE FARM TEAM.**—The following paper was contributed by Mr. W. Zaenker:—"The horse used for farm work should not be too heavy but of a good upstanding type, and active in appearance. The horse that is not too heavy in the legs will stand a day's work better than a clumsy one. Fine horses are the country's pride, and are a better proposition than the tractor in these times. After a day's work the horse when let loose will first go for a drink, and there should always be plenty of water handy. After it has sufficient water the feed is the next. For that there should be proper mangers so that the feed remains clean and also in such a way that they cannot throw out half of the feed. To protect horses from the wet and cold a good stable is essential, a straw roof preferable, if possible; it is cool in the summer and warm in the winter; it will greatly help to keep the horses in good condition and health. Working horses should be given plenty of time in the morning to have a good feed before going out to work. When on heavy work they should be well fed and looked after. The use of the currycomb every morning after the horse has had a heavy day's work the day before will greatly improve the appearance of his coat. Horses kept in fair condition will, as a rule, need less feed. Short hay is better to feed than that from a rank crop. If straw is to be fed, chaffcutting is the better proposition. In the busy time of the year horses should always be given corn, to give them more heart. They should be watered at least four times a day, if possible. Pay particular attention to the harness. The collar should always be cleaned before using after a spell; each horse should have its own collar, and it should fit perfectly. If sore shoulders appear, it is not always necessary to give the horse a spell. Try another collar, it will sometimes allow the sore to heal again by working. The chains of the individual horse

should be of the same length, and all swings adjusted evenly, so that every horse pulls its share, which will greatly minimise sore shoulders. Do not forget to give attention to brood mares, because the next team depends on them. In the latter part of the season they can be worked to within a few days of foaling. When working them, they should always be on the side of the team and not in the middle. Horses should always be treated kindly, but at the same time firmly. Horses generally respond to kind treatment; occasionally one shows bad habits, but these are generally the result of mishandling during breaking in. The best time to educate a horse is when breaking them in. I have a dislike to using the whip, especially in the team, and usually manage to get a fair amount of work done without its use. As is good advice with the tractors so with the horse team, 'under loading is preferable to over loading.' 'Discussing the paper, a member stated that for sore shoulders kerosene mixed with lard was very effective, it kept the sore soft and did not allow a hard crust to form over the sore. To ease a collar over the sore put a few stitches through the lining and pull towards leather firmly, leaving a hole over the sore. In feeding, the following suggestions were offered:—Crushed oats and bran; crushed peas; boiled wheat for aged horses (using half boiled wheat and half chaff). (Secretary, Mr. E. Wurst.)

#### MORCHARD (Average annual rainfall, 13.50in.).

May 1st.—Present: Eight members.

MIXED FARMING AS A MEANS OF ECONOMISING.—Mr. P. Schultz read the following paper:—"The time has come when farmers must take into consideration increased taxation and low prices for products of the farm. Wheat growing alone is being carried on at a loss, so also is sheep. By combining these activities farmers can make a better living at a much less cost. A farmer having a few cows, sheep, poultry, and pigs, and any other sideline has a chance of making a living as he goes along, and one will be surprised at the end of 12 months at the manner in which the expenses have been kept down. By careful management, saving, and a little extra work, the farmer will be able to cut down liabilities to a great extent. Farmers, as well as the rest of the community, have been living right up to their incomes. On almost every farm one can find old implements, but instead of rebuilding these at a small cost new machines were ordered and the old ones discarded. Farmers who are the best off are those who have been the most careful. If the holding is developed as a mixed farming proposition, I believe the farmer will be much better off." Mr. B. McCallum thought sidelines were often neglected until prices for wheat and wool slumped. Mr. Lang thought that the average machine was not built to be mended. Mr. Kupke said his experience was that when cropping 600 or 700 acres of wheat and running 1,000 sheep, sheep gave the better return. Mr. A. McCallum thought that most old machinery, by the time parts and wages were paid for remodelling, would be half the price of new machines. (Secretary, Mr. A. McCallum.)

### MIDDLE-NORTH DISTRICT.

#### (PETERBOROUGH TO FARRELL'S FLAT.)

#### KOOLUNGA (Average annual rainfall, 15.52in.).

May 4th.—Present: 16 members.

WORKING THE FALLOW.—Under the title "Items of Interest" the following paper was read by Mr. H. Spencer:—"During the past few years there has been much discussion on the methods of fallowing and quantities of super sown per acre, and unless we make a careful study and keep a watchful eye over the results we shall be none the wiser. With present prices it is only with careful reckoning up of costs that we are going to prove the most economic way to work, and thus live in hopes of balancing our budgets. I have been an advocate of the cultivator for breaking up land for fallow, and I am still convinced that on most classes of land, and especially on the heavier land, it has once again proved itself at reaping time in results. For breaking up land for fallow, the cultivator can be worked for practically half the cost of the plough, thus making a substantial saving in expense. The work can be completed in less than half the time, thus assuring an early completion of the fallowing, and, as the result of early fallowing has stood out bushels to the acre in advance of late fallow during the past five years, it leaves nothing more to look for from that source. Twelve months ago last harvest, with tests carried out in plots of various super, the double quantity of super per acre showed a profit of 10s. 9d. per acre. Last year we did not sow any plots, but drilled in a few rounds in various pieces to see what the results would be. On one piece, in which we were able to check the results fairly accurately, the heavier dressing, equal to 180lbs. of 45 per cent. super per acre, returned a little over 3bush. more per acre. On working out the cost of super per acre (8s. 5½d.) compared with 84lbs. 45 per cent. (3s. 6½d.) and wheat at 1s. 9½d. per bushel, leaves a small profit of 5½d.

per acre. This looks as if it is not worth the extra manure, but we must remember that if wheat was worth 5s. per bushel it would be showing a profit of 10s. 1½d. per acre. One remarkable feature was that during the dry period in September last year, when the wheat was making for head and some of it trying to get out of the flag, where the heavy dressing of super was applied, the crop was heading very well, but on the lighter dressing there was not a sign of a head to be seen, and the crop was feeling the effects of the dry weather very severely. (Secretary, Mr. E. LePage.)

CALTOWIE (Average annual rainfall, 16.85in.).

April 27th.—Present: 32 members.

**MODERN METHODS OF FARMING.**—Mr. N. Royal presented the following paper:—Farming methods employed by the pioneers of Australia are vastly different to what they are to-day. First were seen the single furrow ploughs, then the double furrows, and it was not so long ago when three furrow ploughs were used extensively. To-day it is not uncommon to see seven furrows and occasionally up to 10 furrows when the farmers have the power available to haul them. The practice once adopted was to plough the land just prior to seeding and work it down with heavy harrows, broadcast the seed either by hand or by machine, and then bury the seed by again harrowing. To-day ploughing is done as early as possible in the winter to allow as much moisture as possible to soak in during the winter rains and to put the soil in good condition to work, in order to get the clods broken down ready for later cultivations in spring. It is then worked with the cultivator to kill weeds, and later on a second cultivation may be given either with the cultivator or harrows. During summer months the farmer has other work to do and can leave the fallow well alone, if it is in good condition with a fine mulch to stop evaporation. When the season breaks sufficiently to germinate weed seeds, I advise the use of harrows to help germination, so that when seeding commences there will be as many weeds started as possible. These can be killed and give the young wheat plant a good chance to flourish. With the advent of super we have the drill, which will sow the desired quantity of seed and super per acre, and then inventive genius gave us the combine, a combination of the drill and cultivator, which is practically universal to-day, thus saving the farmer money, inasmuch that besides having a seeding implement, he also has the cultivator, which can be worked independent of the sowing mechanism. The combine needs only one man and one team (or tractor), whereas if cultivator and drill are independent machines more labor and more power are required to do the work. The latest improvement in farming in recent years is the treatment of seed wheat, which is of vital importance. Once farmers were not so particular over this as they might have been. They took seed from any heap in the paddock and very often, having been reaping two varieties of wheat and emptying at the same heap, the seed became mixed. At other times varieties were mixed by not cleaning the machines when changing from one wheat to the other. Another mistake made is in not selecting the best sample of the plumpest grain with the least cracked grain and weed seeds in it. Having selected the seed, the earlier farmers cleaned it by means of the wind which blew away the chaff, and the next step was the invention of the winnower, which also employed a blast of wind to carry away any light matter, and even with these machines the seed was made clean, but was not of a uniform grade. Just prior to sowing, the seed was pickled in a solution of bluestone or formalin. With bluestone, the pickling can be done in a 10 per cent. solution some time before seeding if it is stacked in the open to dry, but using formalin it must be sown immediately. To-day's method is to clean and grade the seed with a grader and pickler in the one operation. With the latest machines practically 100 per cent. efficiency is obtainable in the extraction of foreign seeds, such as barley and oats, leaving only the best seed for pickling. This is done mechanically in a dustproof container by the use of copper carbonate at the rate of 1½ozs. to 2ozs. per bushel of clean, graded seed, the container being built into the grader in such a way that the wheat is delivered to it in one continuous stream, as also is the copper carbonate, which can be regulated to give the desired quantity. The pickler revolves, which causes the wheat inside to be continually moving and falling about, thus creating a fine dust of copper carbonate to be present, which adheres to the grain, which is then delivered to chutes for bagging. The seed is then ready for sowing or may be stored without in any way affecting its germinating powers, whereas with wet methods the germinating powers of the grain were impaired, especially when strong solutions were used for wheat badly affected with rust. The advantage of dry pickling and grading is that the seed germinates more quickly, the plump grain being able to feed the young, tender shoots and give a more robust plant and a healthier crop which is more able to resist disease and dry spells. Fallow having been well prepared with as shallow a seed bed as possible, the seed is then sown so that it falls on this firm seed bed, which, if there has been a fine mulch covering it, will be moist and will start the seed to germinate and flourish. The successful farmer having worked his land well, and sown the best of seed, pickled dry, in a shallow seed bed, has the evidence before his eyes of good farming methods employed, and thinks of how he is to gather in the harvest. The hay crop in earlier days was cut by the sickle, and later with the mower, raked

together by a horse rake, cocked, and then carted loose. Operations now are easier and quicker. The binder has been with us for some years, and has well earned its place on the farm. Reaping is done with a header and reaper-thresher, either power driven or used with horses, which gathers the heads, threshes the grain out of the head, and cleans and delivers the wheat to the grain box or bags. This is a big saving in time and labor to the now obsolete methods, such as threshing with flails and cleaning with the wind and then bagging, or the later method of using strippers and winnowers, the latter being hard and rather disagreeable work. One advantage with stripping and cleaning with the winnower is that the cocky chaff can be saved for feeding purposes through the winter, and in cases where hay cuts have been light, to supplement the hay. I have purposely refrained from bringing tractors into these remarks previously, because it is, or was, a vexed question among farmers, but I maintain that, could we get more for our products and cheaper fuel as in previous years, power farming is an improvement on the old method of horse traction. It enables farmers to crop more, do their work more expeditiously, with the consequent better working of the land and the saving in wages of employees, and the curtailment of much uncongenial work, such as chaffing, grooming, harnessing, and cleaning out stable yards, allows the farmer more time to devote to side lines or experimental plots, and to keep in touch with the latest agricultural practices." (Secretary, Mr. R. Wilkinson.)

### LOWER-NORTH DISTRICT.

#### (ADELAIDE TO FARRELL'S FLAT.) BUCHANAN.

May 1st.—Present: 12 members.

**MODERN METHODS OF CLEARING HEAVY TIMBER.**—Mr. L. Bell read the following paper:—"With high land values it is essential that every available acre be brought under cultivation. Providing that the timber to be dealt with is green, ringbark all trees large enough and leave until all timber is dry, which takes about three years. In the meantime, keep the block well stocked with sheep, which will keep down all shoots, and the stumps will eventually die. Then, after harvest, as soon as it is possible to burn, get busy with fire and axe. Do not go through the scrub and light a fire indiscriminately, but start in a systematic way by firing first, say, one or two acres. As the trees burn down, keep rounding up the branches and trunks on to the stump, which will finally burn out. On stumps that will not burn out readily, cart dry horse manure, which is very effective. In the case of very solid stumps that refuse to burn out, use a few plugs of dynamite or gelignite. For a stump or tree, say, 18in. to 24in. in diameter, use about three plugs. To be most effective, take 1½in. to 1¼in. auger, bore the hole in level with the ground at an angle of about 45 deg. down into the stump to a depth of about 15in., and then the fire will do the rest. To clear land which is to be put under the plough straight away, the grubbing machine and tractor can be used. When the ground is soft, the tractor is a very quick and easy way of pulling down small trees and stumps up to, say, 1ft. thick. When doing this work with the tractor, one must bear in mind the fact that a machine is being used which costs perhaps up to £500. For timber which is too large for a tractor, it is necessary to use the grubbing machine, which, though effective, is very hard work. The job of pulling down finished, the tractor is again a very useful power unit for dragging away trees or stumps from the piece of land to be ploughed. These can be pulled off on to reefs or any such places, where they can be burned up when dry." (Secretary, Mr. L. Bell, Marabel.)

#### NANTAWARRA (Average annual rainfall, 15.90in.).

April 30th.—Present: 10 members.

**THE HORSE IN AGRICULTURE.**—Mr. R. Nicholls read an article on this subject, and in the discussion that followed, Mr. C. Nicholls thought the national aspect of the subject was very important, but if it made the balance on the wrong side of the ledger it became a personal one. When good horses were from £50 to £60 each, and chaff £8 per ton, a tractor was a reasonable proposition. There were places on the farm where the tractor would beat a horse team. Mr. W. Starkoy said that Australia was subject to drought, and in such times the tractor was cheaper. A tractor very often did two men's work. A tractor owner should do his own repairs if possible. Mr. R. Nicholls said at the present time horse feed and wheat were cheaper, but tractor fuel the same price; this, together with heavy depreciation on the tractor, was a factor against power farming. Mr. E. Hamdorf said a crossbred type of horse was best for farm work. The present was a lean period for tractors, but they would again return to favor. Mr. F. Nicholls said the tractor farmer was sometimes over capitalised, the tractor cost from £500 to £600 when a good horse team could be purchased for £200 to £250.

## OWEN.

April 27th.—Present: 11 members.

**FARM BOOKKEEPING.**—The meeting took the form of a Question Box. A keen discussion arose on the question "Farm Bookkeeping," and opinions were in favor of a ruled ledger. The unanimous opinion of members was the value of keeping all farm accounts most accurately. Mr. Bowen stated that if farmers kept a record of their incidental receipts and expenditure in the "rough diary" usually kept by farmers to record sowings, rainfall, seasonal conditions, &c., their books would be kept far more accurately. Mr. Doyle stressed the advantages of elementary costing as applicable to the farmer. Various questions were then asked and replied to by Messrs. C. Marshman and P. Doyle on the "marketing of eggs" and the advisability of washing a soiled or dirty egg. A further interesting discussion arose over "power farming," opinions being in favor of tractors with the return of better prices, but under existing conditions everything was in favor of the horse, although tractor owners thought it advisable to incur a little expense and rush seeding operations. (Secretary, Mr. H. Bowyer.)

## PENWORTHAM.

April 2nd.—Present: Nine members.

**EUROPEAN AGRICULTURE.**—The Hon. Secretary, Mr. C. Jenner, read the following paper:—"What strikes the Australian most is the old time methods of agriculture in use, but on examination these are found necessary to the climatic conditions, for the Australian harvesting machinery could not be used to advantage. In seeding, part of the acreage to be cropped is sown with fall or winter wheat, sown in late November or early December. This lies under the snow until the spring thaw in March or April, and then the plants push rapidly ahead. After the thaw, farmers busy themselves with the seeding of spring wheats. Stubble land which has been fallowed after reaping is disced or cultivated and drilled in, and other fields are ploughed and sown. Seeding usually finishes about the 21st of May, therefore, fall or winter wheat has about eight months in which to grow and mature, and spring wheat about three months. Growth is very rapid during April, May, and June. Haymaking begins about the 20th June—grass or meadow hay. This consists of grasses and clovers of many descriptions which when carefully treated make excellent hay. None of the fields sown with wheat, oats, or barley are cut for hay; they are strictly reserved for grain and straw which in these densely populated cold countries has a fair market value for thatching stacks, stables, cottages, stock bedding, and fodder. All bean or pea stalks are saved for the same purpose. It is also used for hatmaking, straw mattresses, &c. For hay cutting in the open grass meadow, an ordinary grass mower is used, in the clover fields either a binder or mower, as the farmer may desire. Timber coppices and rough ground are cut by scythenmen. Reaping commences in July, the fall wheat then being ripe and ready; by the time the fall wheat is cut the spring wheat is ready for the reaper. On the larger farms binders are used, the small holder usually reaps by hand, i.e., scythe and cradle, or reap hook, and very often threshes by hand, using the old time flail. Following the reapers come the stookers. The method of stooking is totally different to that practised in these districts. Stooks are placed in straight lines across the field about a chain or more apart, and are not stood upright as we do our hay. The sheaves are placed in a circle, butts outward, heads into the centre, about six or seven sheaves high. A thatched roof is then placed over each stook by inserting a sharpened stake in the centre around which straw thatch has been bound to extend for a radius of 2ft. or more. This makes the grain stook weather-proof. The reason for placing the stooks in straight lines is easily understood when I tell you that the following plough follows the reapers closely, before, in fact, but little of the crop has been carted; singles, double, and three furrows being used similar to our orchard ploughs, but heavier. Stacking in European countries has become a fine art. Some round, others oblong, or square, but all are built on the butts out principle; when a layer of sheaves is completed only one row of heads show in the centre of the stack, so the stacker as he proceeds with the next layer is not treading out grain as he would otherwise do. The stacks are about 40 tons, or about the amount a threshing machine will finish in two days or thereabouts. On the larger farms steam threshing plants are used, many of these are portable and travel from farm to farm, a 6 h.p. portable steam engine being used. Coal is cheap and water plentiful. A team of six horses can shift the whole plant—three for the engine, two for the threshing machine, and one for the trolley. Others on a smaller scale use horse driven machines with a treadmill—the horse attempts to climb a lathed elevator belt, each step pulls the belt back under his feet, this elevator belt drives a shafting on which is a pulley belting from this to the machine. Two fresh horses are used for every run. English flour mills are chiefly water driven, a water wheel and race are used. To construct the race a dam is thrown across a creek or brook, a channel is then cut from the dam to pass under the mill and back to the original stream. A bend in the brook is usually chosen for this purpose, and for safety, floodgates or sluices are inserted in the dam wall. The pressure and

speed of the water in the race drives the wheel fast enough to keep all machinery going at a reasonable speed. A few were electric or steam powered roller mills. Roasters are attached to the mills, for very often the local grain is too soft for grinding purposes without being first dried. The mills in France are on the same principle, except that the village mill is common property. It is wind driven, and is liftive. Built on a pivot mast, it is driven by four lathed sails about 10ft. long and 1ft. wide. All grain has to be carried up a ladder to the grinders, a calico pipe conveys the product to the bagger on the ground; the product is much coarser than that of their roller mills. A long pole from the mast, to which is attached a windlass and chain, the chain is looped over a post in the ground, and by this means the whole concern is winched around to get the sails in line with the wind. *Manures*.—On swamps or marshy lands marl was used to the extent of 8cwts. per acre. Marl very much resembles our gypsum. Leaf mould is also extensively used, practically on all classes of soil. Superphosphate and nitrate of soda, stable and other natural manures, of which European countries have large quantities, are extensively used—nothing is allowed to go to waste. All stock in Europe have to be stabled during winter and heavy straw bedded, so the supply of stable manure is good."

#### SADDLEWORTH (Average annual rainfall, 19.60in.).

May 1st.—Present: 14 members.

**DIFFICULTIES OF THE FARMER.**—Mr. A. Marrett read the following paper:—"The financial predicament that farmers find themselves confronted with to-day has not been brought about solely by the low price for wheat but rather a combination of difficulties. Wheat 34 years ago was sold as low as 1s. 3d. per bushel at Auburn. I propose dividing the paper into five parts, as follows:—(1) Over capitalisation; (2) Indirect taxation; (3) Low prices at present ruling; (4) A departure from farming methods; (5) A lack of confidence in themselves. (1) The plant, a farmer nowadays uses is unnecessarily large and costly. Perhaps a little more wheat per acre in bushels may be sown at the present time, but modern machinery is not playing any part in the increase, rather is it the influence of enterprising farmers and scientific methods, not the machinery. Since the departure from the stripper and winnower, farmers are no better off financially, while many farm laborers are infinitely worse off through lack of employment. All sections are worse off, including the farmer, especially when large commitments on account of modern machinery have to be met. Particularly do I refer to users of tractors and the imported fuel they consume; our imports until recently have exceeded exports, and the farming community has had a big say in this. If stock is taken, the modern or recent trend has been to get as much done as possible without using outside labor. I am quite cognizant of the fact that certain factors regarding the past conditions of labor have had a certain amount of influence to drive a farmer or employer in this direction. (3) Low prices, as I have endeavored to point out, are not solely responsible for the conditions. There is no doubt that the sudden drop has upset the balancing of accounts of the most prudent, which leads one to the fallacy of having 'all your eggs in one basket.' (4) The departure from real farming methods. A farm at one time was never complete unless there were sheep, cows, pigs, and poultry. Many who have been sadly hit at the present time would greatly appreciate a few cows to milk and a small consignment of lambs, wool, and pigs. There is still a profit left in pigs and a big market to explore. Wheat farming was all right while we had inflated prices. Many farmers are paying high prices for cows. These farms had eight to 12 cows previously to the inception of inflated prices for wheat. (5) Lack of confidence. There appears to be a section of the community who think the younger and present day farmer is not imbued with the spirit of their predecessors in this country. With this I do not agree. The young people of to-day will get down to the so-called drudgery, and if many of the older farming fraternity had kept good cows, the younger generation would have had some encouragement to go in for dairying. Anyone who has the handling of dairy stock will take a much greater interest in milking if they have good cows to milk. With good cows dairying is not a drudgery, but a very interesting and profitable occupation. At the present time a farmer can grow and crush his own wheat, oats, and barley, and feed same very profitably to cows. Take five bags of wheat and five of oats; and add 2s. worth linseed—about £4. A good cow will pay for this in a month. In that way one could feed a cow about 8lbs. to 9lbs. of grain a day for seven months. Her skim milk will more than pay her paddock fees and chaff bill, leaving a reasonably good margin of profit for her owner. At 1s. per pound for fat, a cow giving 380lbs. fat would net the owner about £10 10s. profit, which is a very conservative estimate." (Secretary, Mr. A. Blundell.)

#### UPPER WAKEFIELD.

April 30.—Present: 12 members and four visitors.

**QUESTION BOX.**—The meeting took the form of a Question Box. The following questions were asked:—"What is the best depth to fallow black soil?" One member suggested 3ins. to 3½ins. Others thought 2ins. would be ample. "Which is the more

suitable for growing a barley crop; land that has been ploughed up, or land worked up with a cultivator?" Members favored ploughing for best results. "Will black ground fallowed in summer time produce a better crop than when fallowed in winter?" Summer fallowing was advocated by most members. "Which is the best breed of cattle for this district?" One member considered Shorthorns as the best for general use, because when they were unprofitable for dairy uses they could be easily fattened and sold as beef. "What is the best method to prevent a nine months' old calf from sucking cows?" One member suggested a piece of motor tyre fastened around the nose with six 4in. nails driven into it at different places. "Which is the best method of picking wheat?" Bluestone pickling was preferred if the bluestone was mixed to the correct strength. Other members favored dry pickling on account of quicker germination. The Secretary then read a paper from the *Journal*, "Book-keeping on the Farm," (Secretary, Mr. C. Neumann.)

Du

VIRGINIA (Average annual rainfall, 17.23in.).

April 1st.—Present: Nine members.

**HUMUS.**—Mr. P. McEntee read the following paper:—"Humus is the name given to decaying vegetable matter in the soil. Unless the supply is renewed by the addition of new vegetable matter, as in stable manure or crop residues, the quantity will gradually decrease. The garden, because of the frequent applications of stable manure, supplemented by deep and thorough cultivation, is usually the richest part of an old farm. Almost any kind of soil can be made fertile in this way. Stable manure forms humus in the soil, and even the poorest soil can be changed to a garden by its use. In its natural state, the humus supply of soils is maintained by decaying roots of plants and fallen leaves. In cases where the soil has a good supply of phosphoric acid, potash, and other essential minerals, the humus tends to increase, crops become heavier, and pastures improve. Where soil is poor and climatic conditions unfavorable, natural residues are barely sufficient to supply wastage, and crops gradually become lighter, until only the hardiest plants survive. Humus confers certain physical benefits on the soil, *e.g.*, it improves its water-holding capacity, it loosens stiff soils, allowing air and moisture to enter; it binds the coarse particles of sand, thereby improving the texture, and, when wet, gives the darker color to soil. Vegetable matter is changed to humus by the action of bacteria, and changes occur in humus. Some kinds can decompose the humus in wet soils in the absence of air, but in these cases decay ceases before it is complete. This incomplete decay causes the formation of 'humic acid,' and 'sour soil' results. This acid accumulates in swamps and peat bogs, not because of the wet, but because air is shut out. When air cannot penetrate soil, the decay of humus does not stop at the production of humic and other acids. By combining with the oxygen of the atmosphere, bacterial changes go further, forming a milder form of humus, and oxidation goes on to completion. Carbon di-oxide and water are the final oxidation products of humus. The final changes involve the disappearance of humus from the soil, but they are necessary. Soil not only requires humus, but also that it shall decay. The amount of humus varies in different soils. In swamp lands it probably forms the bulk of the dry samples. In ordinary soils, it is generally under 5 per cent. Because free access of air hastens the decay of humus, cultivated land will soon contain less humus than grazing lands. Herein lies the reason for resting farming land. Sandy soils usually contain less humus than clays, because they are pervious to air, and therefore the humus supply is burnt up more rapidly. Lime stimulates bacteria that cause decay, and so soils deficient in lime will often contain more humus for that reason. Finally, high temperatures and open soil hasten decay of humus. Soils of arid districts contain about 1 per cent. as against 4 per cent. humus in wetter areas. But while cultivated, sandy, lime, and arid soils contain less humus, they can, for chemical reasons, afford to contain less because owing to the rapid decomposition in these soils, the benefits are more quickly realised. Chemical changes which take place in the decay of humus cause the formation of nitrogen, which in itself is insoluble in the soil. This nitrogen of the humus must first be changed to simpler compounds. Ammonia and nitrates are two of these. Nitrates are the more effective form, and are the only form with which crops reach full development. Therefore, the production of nitrates within the soil is necessary to successful cropping. Nitrates are produced by bacteria of various kinds. One kind attacks the nitrogen of humus, and ammonia is the result. Other forms attack ammonia and nitrates result in the course of a few weeks under favorable conditions. The manufacture of nitrates within the soil is known as nitrification. Certain conditions are necessary:—(1) Soil nitrogen must be present, *e.g.*, as in humus; (2) the bacteria must be present; (3) fresh air (no nitrification in clay subsoils); (4) darkness (sunlight stops or kills organisms); (5) A suitable temperature (stops in cold weather); (6) sufficient moisture (stops in long, dry spells); (7) carbonate of lime or some other base must be present. It will be seen, therefore, the humus of the soil is important to the farmer, grazier, gardener, and to all those connected with the land." Mr. Lang said the practice of heaping up fresh stable manure resulted in burning out the best qualities of the manure and left only the waste. It was best to apply it to the soil immediately. (Secretary, Mr. W. Lang.)

(TO BUTE.)

**BRENTWOOD** (Average annual rainfall, 15.52in.).

Ten members attended the meeting held on April 2nd, when a paper, prepared from Departmental literature on the subject "Facts About Wool," was read by Messrs. J. and M. McKenzie. (Secretary, Mr. G. Tucker.)

**KILKERRAN.**

May 5th.—Present: 10 members.

**SIDELINES IN RELATION TO PRESENT TIMES** was the title of the following paper by Mr. C. E. Heinrich:—"No subject connected with rural education or industries is receiving more publicity by Bureau Conferences, discussions, instructors, and researchers. Journals and newspapers of all descriptions have their distinctive spaces crammed with information gained from experimentalists and researchers from all parts of the world. America is outstanding in the enormous amounts of money expended for research and rural education. Southern European countries are amongst the foremost in practical work done in dairying and pig raising, and associated industries. The finer arts and knowledge of these occupations have taken years of sound work to acquire. There is no doubt that we forge ahead through their hard-earned information. However, it is particularly necessary to try out, under our own circumstances and climatic conditions, acquired knowledge and especially of breeds of stock. Before the advent of super phosphate the country community was practically dependent on the income from sidelines, and their products found a ready local market. With the improvement of conditions the agriculturists, whose incomes grew, specialised more on wheat and wool and neglected the smaller sidelines more and more, until to-day our main sources of income, produced under peak cost of production, have reached a record low price. Circumstances again force the wheatgrower to see his folly of backing only one horse and to turn his face to the issue of sidelines, paying attention to petty cash, which to-day is worth more than a 1930-31 wheat cheque produced at a loss. During the last two years the fact has gradually dawned on the farmer that his general living expenses

were being left unpaid, that the proceeds of his crop would not cover the liabilities incurred for cropping. This state of affairs is creating a general rush to varied sidelines (principally dairying and pig raising), which action will have to grow steadily, or the markets will be glutted. To enumerate sidelines, they come under two distinctive headings—cereal and stock—the two being closely associated. The growing of cereals, other than wheat, proves necessary for the economic feeding of stock. Yorke Peninsula's sideline—Prior barley—can be termed an industry, being capable of ripening this cereal with distinctive malting quality, but this barley proves an excellent feed, finding ready sale when not up to malting quality. This grain or Chevalier varieties could often be grown in other parts of the State for feed, as it is preferable to the six-rowed or Cape family. Oats grow freely in all agricultural parts of this State as secondary crop, and should be made far more use of instead of risking wheat in many instances—feeding well to all stock and even poultry. These grains are well known, and also have commercial values, but there are other cereals and grasses that are realisable growers and would prove of value to cultivate just for the purpose of fodder and grain feed on the farm. Rye is well worth a trial as sown for feed, grazed, and then reaped. Lucerne, the most hardy of legumes, is most suited for our moderate rainfalls and could be grown in small patches. Stock sidelines are principally horses, cattle, sheep, pigs, and poultry. Horses can be included in this list, as the judicious selection of several mares for breeding would be an addition to plant, upkeep of depreciation, and the source of a little income when disposing of a horse. Dairying has developed in the closer settled areas, and has been neglected by the average wheat grower until recently, and those who are turning to cows have to buy and pay dearly for them, whereas, had we kept our end up we would have young stock growing into production. The cow is the most direct source of income (without risk of outlay) we have. The duties of the farm dairy invariably fall to the farmer's wife, and should not be overdone; yet the number of cows kept in most instances could be increased. Apart from the cow a little can be made out of rearing calves for beef. In that case the Milking Shorthorn would prove more profitable than the Jersey. Upkeep of a milking strain is most important, and bulls of proved breeds and studs should be bought, the Government subsidy assisting in the purchase; or several farmers in company would also make it much easier financially. The sheep is an animal kept for many purposes—a scavenger on fallows, giving a return on wool, a supply of mutton, and most important, the breeding of lambs. Sheep have decreased in numbers in the better agricultural areas through the wheatgrower diverting from the general rule of a crop every three years to one every two, but I am confident that it will be profitable to encourage more grazing. Wool, in normal times, has always given the farmer a nice return, but we are apt to drop one system for another, as during a previous slump in wool South Australia worked up quite a nice lamb trade, but when wool boomed we neglected the breeding of early maturing lambs and reverted to wool breeds, thereby losing our overseas market. The Comeback ewe is the best farm breed, but our flocks are too small to breed them up. The best proposition is a big, clean-faced Merino ewe mated to a popular English breed. Pigs are usually on most farms for bacon and ham, but raising and fattening has not been carried on to any great extent. Educational work and experiments with breeds and types has encouraged the farmer to retain grain (on account of low prices) and attempt pig raising more extensively. Southern European countries specialise in certain breeds, and with care it will be quite possible for us to produce the ideal bacon pig by means of growing a sow produced from the coarser and over-fat breeds to cross with the Large White boar. Poultry is easily kept on a farm. The fowl becomes more profitable with proper care, and produces a regular income. Breeds are numerous, but the Black Orpington appears the most popular. Proper feeding of all stock is essential. Never forget the fact that an ill-fed beast is unprofitable. Provision of roughage is necessary for the winter months, and a quantity should be stored for dry periods. Study time and convenience in arranging yards and automatic feeders for pigs and sheep, so that your time in busy periods is not unduly taken up. Do not plunge into sidelines extensively, as initial cost is a big consideration; rather purchase something good and breed up your stock, your knowledge increasing with the numbers. There are three important factors associated with the increase in stock sidelines—breed, development of markets, and continuity of supply. There is a danger of over-production, which proves a greater difficulty than under supply, and compels the seller to produce the suitable trade type where otherwise the secondary types sell. This stresses the need for consideration of breed, as in the case of pigs. The State's production is equal to requirements, therefore overseas markets will have to be developed to gain access to the London market (which consumes an enormous tonnage of cured and uncured meats). It is essential to produce an article to compete against the world's best—produced, finished, and packed by specialist; therefore our one aim in pig raising must be to produce a type suitable

for export. Breed in dairying and poultry does not so directly influence the saleable product. We must deliver a clean, fresh article, the rest of the responsibility rests on the manufacturer and exporter. The lamb trade calls for extra care. Nothing but good breeding and feeding of a lamb produced from the popular Down breeds, maturing quickly, retaining its freshness, with fleshy, thick-set carcass, can regain the export lamb trade which we held and so foolishly gave up through our own neglect. This sideline, as with pigs, calls for specialising of breed and standardisation of type and weight. We must do our share of advertising overseas, but the quality of the article in show is the finest advertisement. The proof is in the eating, and a satisfied customer will always come back. My third factor—continuity of supply—is just as important as the production of quality. Australians in the past, when they had held a good, steady sale for an article afterwards dropped it for something a little more profitable, thereby letting another country cater for the market. This has been a hard lesson in many instances, and proves detrimental when we offer first quality goods in London. The buyers doubt our ability of continuity of supply. We have paid dearly for erratic production. Our position would not be as bad to-day had we worked and kept our sidelines through normal and boom times when wheat at 6s. lured us from the paltry sums which will take us two or three years to work up. Never lose sight of the fact, when we do gain our share of London's produce market and cereals rise in price, that consistency always wins the day. (Secretary, Mr. A. S. Dutschke, Maitland.)

#### PETERSVILLE.

April 28th.—Present: Seven members.

**ECONOMY.**—The following paper, "Economy on the Farm," was read:—"In the past many farmers have not given enough consideration to general economies. Farming machinery has been very expensive for quite a number of years. Machines that cost large sums of money should be worked by men that understand them. The farmer should give personal supervision at short intervals, and, above all, he should see that the machine is put under cover. Weather-beaten implements, especially the timber portions of them go out of shape. Every farmer should give serious thought before purchasing a new machine. One often notices much neglect of livestock. It pays to look after all animals really well. If horses are left to do all the work, 10 well cared for will take the place of 12 neglected ones. Cows are worthy of good feed and attention. Apart from the produce sold they keep the household in butter, cream, and milk. Some fowls should be kept, providing they are of good laying strain, otherwise they will eat more in grain than they produce. Every farmer should keep sheep, if for no other reason than to supply the house with meat. The tendency to-day is for the farmer to do without sufficient labor, consequently fences, outbuildings, &c., and in many cases cultivation of the soil is neglected, necessitating considerable expense in putting the improvements in repair again and probably a loss on the crop. If farmers try and become good buyers, average business men, thoughtful and careful managers, they will become economical farmers." Secretary, Mr. A. G. Dutschke, Ardrossan.

#### WESTERN DISTRICT.

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

March 31st.—Present: eight members.

**THE PIG-RAISING INDUSTRY.**—An article on this subject was read, and a good discussion followed.

Meeting held April 28th. Present: 10 members, five visitors. Mr. H. D. Adams (District Agricultural Instructor) delivered an address on "Pig and Fat Lamb Raising." He said the low prices of wheat and wool were causing farmers to go in more for sidelines. The sideline prospering most at present was dairying. Cows at present were very scarce and bringing high prices. He favored fat-lamb raising to pig-raising owing to the uncertainty of the local and overseas markets for pork and bacon. England consumed annually £50,000,000 of frozen meat, and of that South Australia exported only a few thousand pounds' worth. For fat lambs, the Merino and Southdown were the best suited, followed by the Merino and Dorset Horn. The ideal bacon pig was the Large White. The dairy cow favored was the Jersey. (Secretary, Mr. W. Cooper.)

GREEN PATCH (Average annual rainfall, 26.56in.).

March 26th.—Present: Seven members.

**THE GAWLER RANGES.**—Mr. L. Derrington read the following paper:—"The Gawler Range, starting from about 70 miles due west of Port Augusta and extending for some 140 miles in length and approximately 50 miles in width, comprises some of the best sheep farming country in South Australia. Enjoying a rainfall of about 9in. on the northern side and 13in. on the southern, the pastoralists have generally been able

to carry on fairly successfully when many other areas have been hit badly with periodical droughts. The Gawler Ranges do not conform to any regular lines of hills, but are broken up into separate hills, or clumps of hills, separated by flats and leads of varying widths. The hills consist of a species of red granite chiefly. The south and eastern sides generally (being away from the hot sun and rough weather) grow edible scrub and grasses, nearly to the top, while the north and western sides of these hills have little else but spinifex (porcupine) sparsely scattered round about the rough granite boulders, and large bare slippery faces of solid granite. In numerous instances, on close examination, these granite faces, apparently solid, show seams often in rectangular formation, and as the ages go by, the rock comes away in large cubic blocks, possibly a foot or more in size, disclosing underneath another apparently solid face. In other instances, these sections of granite stand out like fingers from the sides of the hills in five or six-sided blocks, varying in length from 15ft. to 20ft. long. Springs are not numerous in these regions, but rockholes of varying capacity prove very useful as a means of catching supplies of rainwater for the sheep man when out on his beat. Mount Yardea is the highest point of this range. Edible fodders are varied. They consist of saltbush and bluebush. These two main shrubs are in many instances getting eaten out, particularly round permanent or main waters. Geranium, barley grass, and spinach are generally plentiful after early autumn or winter rains, the two former herbage being very fattening. Geranium particularly is good right to the last when nearly black. Speargrass also makes a very fine show after August and September rains, and frequently the flats present miles of this waving grass. Speargrass is of far less nutritious value than most of the other grasses, except silvergrass, which is of little practical value. Speargrass also causes considerable eye trouble amongst lambs. Overhead fodders chiefly are the myall (which same is the best fencing material for durability), sandal wood, wild peach, bullocky-bush, and mulga. The droppings from all these trees are readily cleaned up by sheep. Mulga and bullocky-bush are particularly appreciated by cattle, and the seeds of the myall are splendid for fattening sheep. This tree, however, does not seed regularly. Spinifex or porcupine, which chiefly grows on the hills on the stony parts, is a very rough fodder, except when in seed about September or October. The seed of this is very fattening for all stock. Bindei is another weed which grows after a summer rain, and provides quite a good feed. *Water Conservation.*—The Gawler Range country provides many good catchments for conserving water in dams, and in most instances good holding ground is obtainable. In one or two instances the big dams are almost permanent. One in particular, a Government dam of big dimensions, has not been less than half-full for many years. Wells are, of course, the natural standby. There are numbers of these, generally of from 70ft. to 150ft. in depth, some deeper, giving respectively sufficient water for from 5,000 to 10,000 sheep. These waters vary in quality from almost fresh to 1½ozs. and 2ozs. of salt; 1½ozs. and 1½ozs. is very frequent, and stock do all right on that. A number of old wells scattered about show evidence of having done considerable duty in past years. These old wells are now too salt for use, and generally have big supplies. They have originally been fitted up with good steam engines, with the necessary sheds, double or triple pump of very solid construction, delivering a 3in. or 4in. flow of water, and stone tanks of circular design, varying in capacity from 20,000galls. to 50,000galls. These tanks, with long stone troughs connected, show evidence of splendid craftsmanship. They are built of granite and cement. Many of them date back to 1870 and 1880, and are in several instances still in good repair. It is stated that these tanks were built at the rate of ¼d. per gallon, and later on 1d. The troughs, often about 100ft. long, have approaches all stone-paved. In regard to these wells, now in disuse, the question arises, that possibly when the stations were in running order in the early days, say about 1860 to 1870, the owners carried such big flocks, and sheep were very cheap, the losses sustained from salt water were not accounted heavy; but in these days similar losses would break the owner, so these old wells have had to be abandoned. The good wells are at the present time, on the better equipped stations, supplying large areas of country (comprising many paddocks) by long lines of piping and force pumps, thus reticulating the water, often to an elevated tank, and then by gravitation to storage tanks and troughs several miles away. This system benefits the stock, the wool, and the country. The sheep are saved a lot of travelling, which at the same time saves the country from being cut up or eaten out and prevents considerable dust, thus keeping the wool much cleaner. Also, reticulating water to the sheep where possible allows of more paddocks being supplied with permanent waters, and at lambing time permits of the ewes being worked in smaller mobs, thus preventing considerable maimothering and loss of lambs, which so often occurs in big mobs of lambing ewes coming considerable distances to water. On the more progressive stations all dams are netted in, and, either windmill or engine with pump, piping, and storage tank are supplied with troughing. This method has two main advantages:—first, by keeping the dam clean, and preventing loss of sheep by bogging when the water is low; also, considerable water is saved, as when woolly sheep enter the water considerable water is absorbed in the wool, and when the sheep goes out of the

dam a considerable amount runs out on the bank and is lost. In the early days paddocks on the big runs were frequently about 10 miles by 10 miles, cutting off 100 square miles in one block, and often only one water. One man had to ride the fences and oversee the stock. That idea is fast giving way to smaller paddocks, particularly where it is possible to make a dam or get a well. Smaller paddocks, and plenty of them, allow the owner to utilise all his country to the fullest advantage. The pure Merino is exclusively bred, and very fine types of sound, robust, and big-framed sheep are reared, growing big heavy fleeces of generally medium strength wool of clean, bright appearance. The average lambing percentage is generally about 75 per cent., and in better years up to 80 and even 90 per cent. Rams are generally allotted at the rate of four to the 100 ewes. The Ranges are generally far more profitable as a sheep-breeding and rearing proposition rather than fattening, chiefly on account of the distance from markets. However, in certain exceptional years large numbers of fine marketable wethers or lambs find their way to either the northern market or Adelaide. Lambing time is changing a good deal of late years. The general rule used to be to start lambing from April to May, but quite a number of owners now lamb in August, the reason being that they were more sure of green feed at that time than at the start of the winter. In good years some owners try a summer lambing about January, thus having some very fine lambs for the following shearing. Shearing time is also changing a good deal of late years. From late August till October generally saw most shearing-sheds in full swing. But now, since the blowfly has invaded the Ranges, many stations shear about February or March, thereby helping the ewes to fight against the sheep fly when lambing in August. About 17 years ago the sheep fly was not known in the Ranges, and lamb-tailing could be carried out without resort to any antiseptics or safeguards of any kind. But the fly is now as troublesome in those drier areas as down in the moister districts. As is well known, sheep farmers up there have their trouble with various pests—wild dogs, foxes, eagles, hawks, and rabbits. The dingo is not quite so troublesome now as formerly, chiefly on account of further outside country being netted in. But every now and again one dog or more manages to find its way through the netting, doing more or less damage. Foxes are very prevalent, especially at lambing time." (Secretary, Mr. C. Whillis, Port Lincoln.)

#### KOPPIO (Average annual rainfall, 22.40in.).

May 5th.—Present: Five members.

Correspondence was received from the Port Lincoln Produce Department regarding the development of the egg, butter, and bacon industries through the Port Lincoln Freezing Works, and invited the Branch to endeavor to supply information as to what quantities of same would be available for shipment through the above works. A good discussion on the subject followed. Members agreed that with profitable prices ruling for same the above lines would be speedily developed in the district, but it was not possible to accurately state any quantities available. Suggestions were made that if advertisements appeared in local papers farmers would realise that dairying and poultry-raising products were worthy of development. The Secretary read a paper, "The Wool Industry." (Secretary, Mr. M. Gardner.)

#### YADNARIE (Average annual rainfall, 14.09in.).

May 5th.—Present: Seven members.

SIDELINES.—Mr. C. Sylvertsen read the following paper:—"With wheat at such a low price it is necessary for farmers to exploit other avenues more fully to assist the revenue from the holding. There are three lines open to farmers in this locality—sheep, poultry, and cows; pigs, in the light of past experience, are not worth worrying about. Sheep are one of the most profitable sidelines. The Merino is the best for this type of country, but there is still room for improvement in building up the frame, also the weight and quality of wool per sheep. The opportunity may be availed of of disposing of a suitable number of lambs for freezing purposes by the use of a suitable ram. Dairying could be improved a great deal, the farmer giving greater attention to the quality and quantity of foodstuffs necessary to give maximum returns for the duration of the whole lactation period. In addition it is essential to give each cow in its food or otherwise 2ozs. of salt and super combined. I favor the Jersey breed. The cows are very productive and require a minimum of feed compared with the larger framed animals. In poultry I prefer the laying strain of Black Orpington or White Leghorn. The careless method of egg collection and the disposing of eggs at the store is a direct loss to the farmer of 3d. to 4d. per dozen. Eggs for market should be infertile, of a standard weight of 1½ozs. to 2ozs., collected once a day in winter and twice in summer, and marketed through an infertile egg association." (Secretary, Mr. E. Spriggs, Cleve.)

## EASTERN DISTRICT. (EAST OF MOUNT LOFTY RANGES.)

### KULKAWIRRA.

May 12th.—Present: 14 members.

Mr. R. L. Griffiths (District Agricultural Instructor) addressed the meeting on "The Farmer's Control over the Cost of Wheat Growing," and stressed the following points:—  
**Cultivation**—Early fallow to be kept clean either by cultivation or sheep. **Correct seed conditions**—A shallow mulch with firm compacted underlayers. **Varieties**—Free Gallipoli: A late wheat. In Victoria Federation has been the leading variety, but last year Federation was 17 per cent. and Free Gallipoli 35 per cent. of the total acreage sown. It suited almost all classes of land. **Mid season varieties**—Currawa, Caliph, and Felix. Joffre was fairly rust resistant. **Early varieties**—Gluyas for hard conditions; Sulton rather bad for rust; and Nabawa, a wheat of outstanding merit, 50 per cent. of the wheat area of Western Australia being sown with it this year. **Questions** were asked about the use of sulphate of ammonia. **Time of sowing**—Mixed with other super and sown with the seed. **Results** are not pronounced on fallow, but on stubble last year at Mr. Sanders, of Yurgo, super gave a hay cut of 2 tons per acre and super and sulphate of ammonia gave 3½ tons, an increase of 30cwt. per acre. (Secretary, Mr. H. Elliot, Karoonda.)

### MILLENDILLA (Average annual rainfall, 13in.).

April 9th.—Present: Seven members.

Mr. R. Hill (Agricultural Instructor) addressed the meeting on "Mixed Farming." The main points stressed were dairying and sheep, the latter being a necessity on every farm. He advocated the use of a Southdown ram mated with a Comeback or a Merino ewe, which would result in a lamb suitable for export. For the local market the Dorset Horn ram with the above-mentioned ewes would be quite suitable. The Corriedale ewe was not deemed suitable for this district, as it was a breed for the wetter districts, to which it was admirably adapted. For dairying, he advocated the making of stack ensilage, for which either oats, barley, or wheat should be sown if natural grasses were not sufficient, which was the case in this district. The cereals combined would make even better ensilage. Only as much as could be carted in the stack every day should be cut the same day. The stack should be 18ft. high at the least when finished. The outside of the stack should be left high and well trampled to prevent air getting in. The inside should be low, just the opposite to a hay stack. A layer of straw should be put over the top of the stack when finished and weighted down with not less than 500lbs. pressure to the square yard. Stones were preferable for this, placed on a layer of red gum slabs or anything else to give a level surface, thereby giving an even pressure all over the top of the stack. Next he stressed the importance of drinking water and shade during the summer months for cattle. The cows should be kept near this and not turned out in a 200 acre stubble paddock to be able to try and fill themselves before night with fodder which contained very little nutriment, let alone produce milk. The cows should be kept near the home and be hand fed whenever necessary. Oats, oatmeal, linseed meal, bran, or chaff were good fodders for dairy cows, and should supplement the natural pasture in the right proportion. Lucerne sown on stubble land at the rate of 3lbs. or 4lbs. to the acre provided excellent greenfeed, or even a small patch of lucerne near the house was just what the cows needed sometimes if it could not be grown on a more extensive scale. He also stressed the necessity for keeping better cows, cows that were worth milking and the trouble of feeding. A good cow would cost no more to feed than a poor producer. Oats sown on stubble land also provided early greenfeed for both cows and sheep, and Mr. Hill thought Lachlan would be the most suitable for this district." (Secretary, Mr. V. Wegener.)

### MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

May 16th.—Present: 24 members.

**CARE OF THE FARM TEAM.**—Mr. C. Paech, who read a paper on this subject, said:—  
"When the team is brought in to start work each horse should be given a good grooming, as this not only adds to their appearance but assists in keeping them in good health. If the hoofs are too long it is advisable to cut them down. This will save considerable trouble, because if the hoof breaks off too deep there is a danger of it causing lameness. When starting the team to work at the beginning of the season take them steady for a few days. At this time the horses are likely to become overheated and develop scalded or sore shoulders. Watch the shoulders, and if one gets a sore shoulder see if there are any lumps in the collar, if so it can be smoothed out with a bottle, or the sore may be due to the draft being either too low or too high. If the shoulders are kept clean and the hair brushed straight and smooth it is not likely that there will be much trouble. **Feeding.**—Regular feeding is necessary to maintain good health, especially the midday feed. It is a mistake to give a long dinner hour and then a short one, 1½ hours to 1½ hours is enough for dinner if it is

regular. In the morning feed at 5 o'clock, and be back in the stable by 6 o'clock in the evening in winter time. Give enough feed, but not so much that they leave a lot in the manger. I prefer giving the team a drink before meals." During the discussion it was stated that it was a wrong practice to turn working horses out into green grass during week-ends; this caused the horses to scour and gripe. It was safe to turn them out every night after feeding when grass was plentiful; they would then be used to it. Horses should not be worked after sunset. It would be quite all right to start early in the morning to work a long day. (Secretary, Mr. C. Altmann.)

#### NETHERTON.

April 29th.—Present: 13 members.

**COWS ON THE FARM.**—Mr. F. Hogood read the following paper:—"If cows are kept for cream production the farmer should endeavor to obtain a good strain of animals, and if these are cared for, fed and looked after in the proper way, they will nearly always show a profit in bad seasons as well as in good seasons. I recommend the Shorthorn cow crossed with a Jersey bull. The Shorthorn is a very hardy breed and, as the Jersey is the best of all breeds for cream production, the cross recommended should produce the most profitable cows. The cows should be provided with plenty of shelter from severe cold winds and rain in winter, and, on this account, it is desirable to leave a few acres of scrub near the homestead. Make regular milking hours and see that each cow gets its fair share of feed. Before starting to milk see that the udder and hands of the milker are clean. Cows are of a nervous temperament and need very quiet handling to get the best results. In feeding for cream production, I prefer oatmeal hay chaff or barley hay chaff cut on the green side. When feeding in the dry period of the year, best results are obtained from good chaff and bran mixed with molasses. Always give the cows a little salt and bonemeal occasionally, it assists in keeping them healthy. A paddock should be reserved near the homestead and sown with barley or rye to provide early greenfeed, and for summer, lucerne and maize should be grown. It does not pay to feed cows that do not show a profit, and do not always blame the cows before considering the feed and the treatment which they receive. Never kill any heifer calves from good cows. If you do not want them, sell or give them to a neighbor. If this is done there will always be good cows available, and the estate and district will benefit. If the management of cows is properly carried out, there is no reason for any farmer and his family to want so far as a living is concerned." (Secretary, Mr. C. Wilkin, Yumali.)

#### OVERLAND CORNER (Average annual rainfall, 10.50in.).

April 28th.—Present: 10 members and four visitors.

**FENCING.**—The following paper was read by Mr. J. Chesney:—"Usually the boundary of the property is marked by survey pegs, so that taking out a straight line is not difficult for the amateur. First put up enough pegs so that an alignment can be taken of them when putting in the posts. It is not advisable to sight the posts of line being put up; always sight them not less than three pegs ahead. *Six-wire Fence, 15ft. Apart.*—To keep stock on the property I advocate a fence of posts 5ft. 4in. long, 12in. circular at the small end, 20in. deep in the ground. Strainers 6ft. 2in. long, 18in. circular at the small end, 2ft. 6in. in the ground. This fence will take 352 posts to the mile. Strainer post should all be placed with bends (if any) towards sight pegs; strainers should be kept hard up against the back of hole. No strainer should have two bends, one forward and the other sideways; this will twist when straining the fence. *Measurements.*—In boring, all posts of six-wire fence should be 5in., 6in., 6in., 7in., 8in., and 10in. apart. Holes should be bored perfectly level. Up and down boring causes uneven spaces in the wiring and makes hard work pulling it in, and so a little care when on the brace will save much trouble. Running out the wire should be done the same way as the posts are put up, so that a leading wire can be strained. The middle one, or the one above should be used for this purpose. When running wire, make the wire fast on the strainer ahead to be strained back. This holds the strainer while the other five wires are being strained. The barb wire should be strained tight enough to just move the strainer on which you are working, the other is hard up against the back of the hole and will not shift. Always strain from the bottom of the post upwards. Should a post give a little it will tighten the top wire. A post would have to give a great deal to slacken the bottom wires. Properly strained wires are most important, if they are slack it encourages sheep to crawl. The length of the strains should not be over six chains, the wires will keep tighter; and should a wire break it does not make such a long gap. All new fences should be strained with a wire strainer or fork. When pinning, see that the back knock of the pin is towards the operator, so that it can easily be knocked out. Knock the wires well in when rounding posts. Keep the wire on the side of the hole when pinning, the wire will

hold better and no slack is lost. Always fasten the wires the opposite way around the post. Do not put all back wires on one side and head ones on the other, but arrange them alternately so that the strainer will not split with the severe strain. Wires should be strained tightly to pull the knots tight. They can be eased off a little, if necessary. This prevents snapping on cold nights, if figure 8 knots are used. Strainer posts at corners should be held in position by stays, which should be at least 10ft. to 12ft. long. They should be morticed in at not more than two-thirds of the height of the post, a little from the centre, to allow room for the wires. The other end should be about 1ft. in the ground with the butt against a solid block placed upright at ground level. Stays fastened over the top of the strainer are likely to lift the post. Where posts are scarce or expensive, fences are often built with the posts 20ft. to 30ft. apart. Light iron posts are sometimes used between the wooden ones, drilled to the correct gauge of the wires. In other cases droppers are useful. There are many kinds of droppers on the market, but the best is the wooden dropper, threaded on the wire and fastened by fine wire at top and bottom. These droppers should not touch the ground, because they are quickly affected by damp and white ants. In some districts fences with cement posts and iron droppers are becoming popular, and, although rather expensive, they make an everlasting job." (Secretary, Mr. J. Löffler.)

#### RAMCO.

March 10th.—Present: Seven members.

**THE BLOCKER'S HORSE.**—In the course of an address, "Care and Handling of Horses," Mr. R. Bell said a horse six or eight years old was best for the blocker. An aged horse was easy to handle, and in most cases could be driven by any driver. The main point in a horse was its feet; if these were defective the horse would never be a good worker. A horse that had been foundered was liable to have a recurrence of this trouble. Leading the animal on a hard road would soon show if it had been foundered. It would hold its head straight forward and carry the feet in a tender manner. Side bone was as serious a defect as founder. Side bone was a coral formation on top of the hoof, similar to a ring. White hoofs were soft and the horse would need frequent shoeing. A blocker required a horse somewhat on the quiet side, with good shoulders and sound feet. One should be careful in taking off the blinkers, because if the horse was touchy it was liable to jump back. If it showed signs of this habit, a rope should be placed around its neck and the blinkers taken off again quietly. A good fitting collar would do much towards saving trouble with sore shoulders. The collar should fit snugly at the neck, with just sufficient room to slip in the fingers. Plenty of good feed was necessary, but one should see that the horse cleaned up its feed after each meal. If the horse slobbered, it was usually a sign of teeth trouble. It was not advisable to only rug a horse in winter. The horse became accustomed to circumstances, and if it was stabled and then turned out in the cold, there would be trouble. Horses were liable to pick up sand in their district, especially when green feed came up. If sand developed, then a good drench, either of coffee or honey and milk, should be administered. A good discussion followed. Mr. J. Boehm thought it a good plan to get a young horse and train it. Mr. F. Lewis said often one could get a horse in the saleyards with feet not suitable for road, but would be quite suitable for the block, especially in this district. The main essential in a block horse was quietness, and if this was wanting the horse was a nuisance.

**HARVEST REPORTS.**—Meeting held April 10th. Present: Seven members. Mr. J. Boehm reported apricots 1 acre, pruned end of May and June. Ploughed and cross-cultivated in October, manured with two bags No. 1 bone manure at first irrigation and sulphate of ammonia one and a half bags. Fruit very good and fair crop; not so good as last year, but excellent grades; only one box of 1 crown in 1 ton. Crop received two irrigations. Nectarines—Crop light, but fruit of good quality. Picked and sulphured same day; not allowed to stand over night; results excellent. Mr. F. Lewis reported:—Apricots fair size. Manured with one dressing of sulphate of ammonia after fruit set—six weeks before picking. Mr. C. Boehm gave apricots 1cw. per acre of sulphate of ammonia. Good quality fruit, but not a heavy crop. Vines—Mr. F. Lewis reported on two blocks, No. 15 and No. 23. No. 15 last year produced a light crop of Gordos and currants. Hot winds in December scorched a lot of grapes and reduced the yield. No. 23 yield was normal. This year results on the two blocks were reversed. No. 15 was 10 per cent. above normal in yield, whilst No. 23 (Gordos) were down 15 per cent., currants 10 per cent. to 12 per cent. down. No manure was used this year, but the plot had been well manured previously. General average of crop was given as currants slightly above normal, sultanas below, and Gordos slightly above. (Secretary, Mr. J. Odgers.)

May 4th.—Present: Seven members.

The meeting took the form of a Question Box evening. Mr. R. Bell asked what is the value of stable manure as a fertiliser for vines? Mr. E. Burroughs said stable manure was not to be excelled for this purpose. Mr. C. Boehm agreed, but said with

INDIAN AGRICULTURAL RESEARCH  
INSTITUTE LIBRARY,  
NEW DELHI.
